Abstract

We extend the Three-Pass Regression Filter (3PRF) by [Kelly & Pruitt \[2015\]](#) in two significant dimensions. First, we account for scenarios where the factor(s) may be weak. Second, we allow for a correlation between the target variable and the predictors, even after adjusting for common factors, driven by correlations in the idiosyncratic components of the covariates and the prediction target.

Our primary theoretical contribution is to establish the consistency of 3PRF in estimating target-relevant factors under these broader assumptions. We show that these factors can be consistently estimated even when weak, though at a slower rate than strong factors. Importantly, we find that stronger relevant factors improve the rate of convergence of 3PRF to the infeasible best forecast relative to Principal Components Regression (PCR), with convergence rates increasing as relevant factors strengthen and slowing with stronger irrelevant factors. This highlights the theoretical superiority of 3PRF over PCR in terms of convergence—a novel result.

Our second contribution is methodological: we introduce a Lasso step, forming the 3PRF-Lasso estimator, to model the target’s dependence on the idiosyncratic components of the predictors. We derive the rate at which the average prediction error from this step converges to zero, accounting for generated regressor effects.

Extensive simulations indicate that 3PRF outperforms PCR under these modified assumptions, with significant gains from the Lasso step, even when only a few idiosyncratic components correlate with the target variable. In an empirical application, we use the 3PRF-Lasso framework to forecast key macroeconomic variables from the FRED-QD dataset, achieving robust performance relative to alternative methods across multiple horizons.

1 Introduction

Factor models are ubiquitous in the econometric analysis of high-dimensional data. Starting from the seminal work of [Forni *et al.* \[2000\]](#), [Stock & Watson \[2002\]](#), and [Bai \[2003\]](#), the utility of these models has been increasingly acknowledged in high-dimensional multivariate analysis. Notably, they have found extensive use in two key areas: high-dimensional covariance estimation and forecasting. This paper delves into the latter domain.

The literature on forecasting with factor models is extensive. Some prominent papers include [Ludvigson & Ng \[2016\]](#), who highlight their effectiveness in financial forecasting; [Stock & Watson \[2002\]](#) and [Stock & Watson \[2003\]](#), who demonstrate their importance in macroeconomic prediction; [Ciccarelli & Mojon \[2010\]](#), who use them to predict global inflation; and [Andreou *et al.* \[2013\]](#), who apply them to forecast U.S. real GDP growth, among others.

The efficacy of these models is well-documented in the literature. [Stock & Watson \[2012\]](#) find that forecasts derived from factor models outperform those generated by several shrinkage-based techniques. [Kim & Swanson \[2018\]](#) corroborate these findings by showing that factor-augmented models generally exhibit superior predictive performance compared to a wide array of machine learning methods.

To introduce the framework for forecasting with factor models, consider a scenario where we have a large number of predictors organized in a vector, \mathbf{x}_t , and aim to forecast a single target variable h -periods ahead, y_{t+h} . In this context, a standard factor-based forecasting model can be expressed as follows:

$$y_{t+h} = \beta_0 + \boldsymbol{\beta}' \mathbf{F}_t + \eta_{t+h}, \quad (1.1)$$

$$\mathbf{x}_t = \boldsymbol{\phi}_0 + \boldsymbol{\Phi} \mathbf{F}_t + \boldsymbol{\varepsilon}_t. \quad (1.2)$$

In this framework, the N -dimensional vector of covariates \mathbf{x}_t is decomposed into three components: an intercept term $\boldsymbol{\phi}_0$, a low-rank component $\boldsymbol{\Phi} \mathbf{F}_t$, and a vector of idiosyncratic components $\boldsymbol{\varepsilon}_t$. The low-rank component captures the systematic variation across the covariates and is driven by the K -dimensional vector of latent factors \mathbf{F}_t , where K remains fixed asymptotically. The $N \times K$ matrix $\boldsymbol{\Phi}$ represents the matrix of factor loadings, which quantify the influence of each factor on the observed covariates. The vector of idiosyncratic components $\boldsymbol{\varepsilon}_t$, as the name suggests, represents variation unique to individual covariates. The variation in the idiosyncratic components of the predictors is non-systematic and cannot be further decomposed into a lower-rank structure.

Certain foundational assumptions are typically made when developing the forecasting framework with factor models. Specifically, the forecast error η_{t+h} is assumed to have a conditional expectation of zero with respect to the information available in period t , the

idiosyncratic components, denoted by ε , are allowed only weak serial and cross-sectional correlation and the latent factors are assumed to be strong; i.e., $\frac{\Phi'\Phi}{N}$ is assumed to have a non-zero limit.

This formulation has three notable drawbacks. First, some factors driving the predictors may be irrelevant for forecasting the target variable. Unsupervised forecasting methods, such as Principal Component Regression (PCR) (Bai [2003], Stock & Watson [2002]), estimate all factors driving the predictors \mathbf{X} and use them to predict \mathbf{y} . Including all factors in the forecasting equation is inefficient, as irrelevant factors (i.e., factors unrelated to the target variable \mathbf{y}) inflate the variance of the forecast without contributing to its accuracy. Second, in equation 1.1, $\beta_0 + \beta'F_t$ provides an optimal forecast only if $\mathbb{E}(\eta_{t+h} \mid \varepsilon_t) = 0$. However, when \mathbf{X} is high-dimensional, it is unlikely that none of the idiosyncratic components ($\varepsilon_i \mid i \in \{1, \dots, N\}$) are correlated with the target. If even a small subset of these components is correlated with the target, the forecast constructed using equation 1.2 is sub-optimal, as all the predictive information in \mathbf{X} is not being utilized to forecast \mathbf{y} . Third, the Assumption of strong factors may not always be valid, as evidenced by various studies, including Bailey *et al.* [2021] and Freyaldenhoven [2022]. When factors are weak, either due to their local nature or weak loadings, the properties of forecasting methods require closer examination. For example, in the case of PCR, additional conditions are necessary to ensure consistency, as discussed in Bai & Ng [2023]. Therefore, any forecasting method that relies on estimated factors must evaluate the impact of weak factors, as the conditions for consistent estimation may differ across estimators. Additionally, convergence rates can vary, with some estimators converging relatively faster or slower under different types of weak factor structures. A closer examination of the properties of different estimators under weak factor settings allows for meaningful comparisons and helps in selecting the appropriate estimator based on the assumed data-generating process.

The first limitation was addressed by Kelly & Pruitt [2015], who introduced the Three-Pass Regression Filter (3PRF), a supervised method that uses ‘proxy’ variables, denoted by \mathbf{Z} , to estimate factors relevant to the target variable \mathbf{y} . Their approach stems from the recognition that the factors influencing the target may form a subset of the factors driving the predictors \mathbf{X} . This filter estimates only the factors that are relevant to the target, thereby yielding more efficient forecasts. Building on their work, our study presents a generalized

framework that relaxes the aforementioned assumptions and introduces an additional step involving the Least Absolute Shrinkage and Selection Operator (LASSO; [Tibshirani \[1996\]](#)) to capture the predictive content of idiosyncratic components. We call this augmented estimator as 3PRF-LASSO.

Few papers in the literature have attempted to address the aforementioned second limitation—namely, the Assumption that idiosyncratic components are orthogonal to the target variable—by trying to harness the predictive content of these idiosyncratic components. Notable examples include [Fan *et al.* \[2023a\]](#), [Kneip & Sarda \[2011\]](#), and [Fan *et al.* \[2023b\]](#). In these works, the factor-based forecasting model (1.1) is augmented by incorporating a small subset of idiosyncratic elements as additional predictors. This is achieved through regularized M-estimation techniques that select the relevant idiosyncratic components and estimate their coefficients, thereby combining two orthogonal approaches for high-dimensional estimation: sparse modeling and dense factor modeling.

Allowing idiosyncratic components to correlate with the target variable reflects the reality of many economic forecasting scenarios, particularly when dealing with a large number of predictors. [Fan *et al.* \[2023b\]](#) provides several examples demonstrating this. [Beyhum & Striaukas \[2024\]](#) introduce a framework for testing a dense model specification, specifically factor regression, against a hybrid model that combines dense and sparse components; a factor model augmented with sparse idiosyncratic components. They apply this test to various macroeconomic and financial datasets, frequently rejecting the null hypothesis. As they note, “This suggests the presence of sparsity — alongside a dense component — in widely studied economic applications.” To further motivate this, consider the study by [Kelly & Pruitt \[2015\]](#), which explores the forecastability of macroeconomic aggregates using a large set of predictors -specifically, 108 macroeconomic variables compiled by [Stock & Watson \[2012\]](#). They demonstrate the effectiveness of the Three-Pass Regression Filter by assessing its forecasting performance, using various variables from the dataset as targets and the remaining variables as predictors. The predictors are assumed to follow an approximate factor structure, as introduced by [Chamberlain & Rothschild \[1983\]](#), accommodating weak serial and temporal correlations in the idiosyncratic components. Although [Kelly & Pruitt \[2015\]](#) do not claim that target variables are inherently distinct from other predictors, their methodology implicitly assumes that the idiosyncratic components of target variables are martingale difference

sequences, independent of other idiosyncratic components.¹ This Assumption implies a strict factor structure for the target variables rather than an approximate one, which is restrictive. Our empirical analysis reveals that idiosyncratic components can indeed exhibit substantial predictive power for certain macroeconomic variables, as evidenced by the enhanced performance of our 3PRF-LASSO method compared to the traditional 3PRF approach.

Augmenting a PC-based factor model to address this limitation is relatively straightforward because the factor estimation process is not influenced by the data-generating process of \mathbf{y} due to the unsupervised nature of principal component-based factor estimation. However, in the 3PRF framework, allowing idiosyncratic elements to possess predictive content for the target \mathbf{y} , and thus for \mathbf{Z} , introduces a form of ‘corruption’ in the supervision process, as clarified in Section 2.² Essentially, estimating factors as principal components ensures that the factor estimation procedure remains unaffected by the correlation between idiosyncratic components and the target, as neither the target nor the proxies mimicking the target are used in the factor estimation. However, within the 3PRF framework, where proxies are used for supervision, correlation between idiosyncratic components and the target can potentially undermine the advantages of supervision. The 3PRF methodology is designed to extract relevant factor loadings from the proxies to estimate factors pertinent to the target. However, when idiosyncratic dependence is present, the extraction process becomes less precise, as it retrieves information that is unrelated to the factors but derived from the correlation between the proxies and the idiosyncratic components. We specify the Assumptions in Section 3 to ensure that this ‘corruption’ does not adversely affect the asymptotic rates of convergence.

The third limitation, i.e., the strong factor Assumption, has also been addressed in recent literature on PCA factors; see Bai & Ng [2023] and Freyaldenhoven [2022]. The primary focus of their papers is to examine the implications of a weak factor structure on PC estimation of factors rather than on forecasting. Bai & Ng [2023] includes a discussion on the implications of using PC-estimated factors under a weak factor setting for prediction when all factors have the same strength.

We extend the theory of the Three-Pass Regression Filter (3PRF) to include settings where predictors follow a weak factor structure. Our framework allows target-relevant factors

¹They assume that $\mathbf{y}_{t+1} - \mathbb{E}(\mathbf{y}_{t+1}|F_t)$ is serially uncorrelated and independent of all idiosyncratic components.

² \mathbf{Z} mimics the data generating process (DGP) of \mathbf{y} in that it depends on the same set of factors and idiosyncratic components as \mathbf{y} . This is clarified in Assumptions 1 and 9.

to have a different strength compared to target-irrelevant factors.³ Our theoretical results provide bounds on how weak the target-relevant factors can be. The lack of sufficient factor strength necessitates a larger sample size T for consistent estimation compared to the case when all factors are strong. Furthermore, if irrelevant factors are too strong, the convergence rate is severely reduced, and beyond a certain limit $\psi_g > 2\psi_f$, we encounter inconsistency.⁴ For instance, if irrelevant factors have a strength of 1, this implies a bound of $\frac{1}{2}$ on the strength of relevant factors.⁵

We establish that 3PRF converges to the infeasible best forecast at a faster rate than PCR when relevant factors are stronger than irrelevant ones, providing insight into why 3PRF performs well in many empirical settings. While Kelly & Pruitt [2015] demonstrates the consistency and convergence rates of 3PRF, it does not theoretically establish any superiority over PCR. Our contribution fills this gap by explicitly identifying cases where 3PRF has a clear advantage. Conversely, when irrelevant factors are stronger than relevant factors, 3PRF has a relatively slower convergence than PCR. However, this scenario is unlikely in practice, as even a single irrelevant factor weaker than the relevant factors complicates the comparison.

Idiosyncratic elements can be viewed as factors with zero strength; they may exhibit local correlations but lack a factor structure. Extremely weak factors with near-zero strength can be treated as part of the idiosyncratic components. Estimating such factors is costly, as their low strength makes accurate estimation challenging or even infeasible in some cases. A practical approach is to use predictors that load heavily on these weak factors as proxies.⁶ This is akin to regression with measurement error, where these predictors serve as imperfectly measured weak factors. The second-stage LASSO step can then select such predictors, thereby indirectly capturing the impact of very weak (near-zero strength) factors on the target variable by selecting variables that load heavily on the omitted weak factors.

Finally, the existing literature on Principal Component (PC)-based factors typically ad-

³Assuming all irrelevant factors to have the same strength is primarily for notational convenience. When irrelevant factors have varying strengths, the theoretical results can be reformulated in terms of the strength of the strongest irrelevant factor.

⁴ ψ_g is the strength of irrelevant factors and ψ_f is the strength of relevant factors, as clarified in Assumption 2.

⁵Factors with $\psi < \frac{1}{2}$ are considered very weak in the literature and not useful from the standpoint of economic theory; see Freyaldenhoven [2022] for further discussion.

⁶The term ‘proxy’ here is used in its more conventional sense, referring to a measurable variable that is used in place of an unobservable predictor, such as an omitted weak but relevant factor. This differs from the use of term ‘proxies’ in the 3PRF framework, which are specifically used to estimate the relevant latent factors.

dresses the issues of weak factors and idiosyncratic dependence in isolation without assessing their combined impact. In the context of the Three-Pass Regression Filter (3PRF), we extend the theoretical framework to account for both phenomena simultaneously. Specifically, we derive the rate at which the regularization parameter in the second-stage LASSO should approach zero asymptotically, with this rate depending on the strength of the factors. The convergence rate of the LASSO step is influenced by the rate at which the LASSO regularization parameter approaches 0, and hence, we provide a more comprehensive understanding of how both weak factors and idiosyncratic dependence interact and affect the model’s performance.

Our simulation results indicate that, under these general assumptions, the performance of the Three-Pass Regression Filter (3PRF) frequently surpasses that of its closest competitor, Principal Component Regression (PCR). The augmented method, 3PRF-LASSO, which combines the 3PRF first-stage regression with a second-stage LASSO regression on idiosyncratic components, consistently outperforms both 3PRF and PCR. In many cases, it also exceeds the performance of PCR augmented with a LASSO step. When N is large relative to T , this advantage becomes almost universal, extending across various factor strengths and serial/cross-sectional correlations in factors and idiosyncratic components. Furthermore, 3PRF-LASSO frequently outperforms LASSO when relevant factors are relatively strong compared to irrelevant factors.

Our empirical application underscores the effectiveness of the 3PRF-LASSO approach. We forecast four key U.S. macroeconomic variables—GDP, Exports, the GDP Deflator, and Housing Starts—using a comprehensive set of macroeconomic variables from the FRED-QD dataset by [Clark & McCracken \[2023\]](#). The 3PRF-LASSO method demonstrates competitive performance compared to established methods, highlighting its reliability in macroeconomic forecasting.

The paper is structured as follows. Section 2 introduces the proposed estimator, detailing its formulation and operational mechanics. In Section 3, we outline a series of assumptions necessary to establish the theoretical results presented in Section 4. This theoretical framework is then put to the test in Section 5, where we explore the numerical properties of our estimator through comprehensive Monte Carlo simulations. Section 6 focuses on empirical applications, demonstrating the estimator’s performance with real-world data. Finally,

Section 7 summarizes the key findings and offers concluding remarks.

1.1 Definitions and notations

Let \mathbf{y} denote the $T \times 1$ vector of the target variable, i.e., $\mathbf{y} = (y_h, y_{h+1}, \dots, y_{t+h})$. We have N predictors, each with T observations. The cross-section of predictors at time t is given by the $N \times 1$ vector \mathbf{x}_t . The temporal observations of predictor i form the vector \mathbf{x}_i . The predictors are stacked in a $T \times N$ matrix \mathbf{X} , $\mathbf{X} = (\mathbf{x}_1, \mathbf{x}_2, \dots, \mathbf{x}_T)' = (\mathbf{x}_1, \mathbf{x}_2, \dots, \mathbf{x}_N)$. We have L proxies stacked in a $T \times L$ matrix $\mathbf{Z} = (\mathbf{z}_1, \mathbf{z}_2, \dots, \mathbf{z}_T)'$.

Define $\mathbf{J}_T \equiv \mathbb{I}_T - \frac{1}{T} \iota_T \iota_T'$, where \mathbb{I}_T is the $T \times T$ identity matrix and ι_T is the $T \times 1$ vector of ones. \mathbf{J}_N is defined analogously. For matrices \mathbf{U} and \mathbf{V} of conformable dimensions, let $\mathbf{W}_{UV} \equiv \mathbf{J}_N \mathbf{U}' \mathbf{J}_T \mathbf{V}$ and $\mathbf{S}_{UV} \equiv \mathbf{U}' \mathbf{J}_T \mathbf{V}$.

Given an index set $S \subset \{1, \dots, N\}$ and a vector \mathcal{X} with i -th component \mathcal{X}_i , define $\mathcal{X}_{i,S} = \mathcal{X}_i \mathbb{1}\{i \in S\}$, where $\mathbb{1}$ is the indicator function. For a set A , $|A|$ denotes its cardinality. For a vector \mathbf{v} , $v(m)$ denotes its m -th component. The norms we use in the paper are:

$$\|\mathbf{v}\|_1 = \sum_i |v_i|, \quad \|\mathbf{v}\|_2 = \left(\sum_i v_i^2 \right)^{1/2}, \quad \|\mathbf{v}\|_\infty = \max_i |v_i|.$$

For an $m \times n$ matrix $A = [a_{ij}]$, the following norms are used:

$$\|A\|_\infty = \max_{1 \leq i \leq m} \sum_{j=1}^n |a_{ij}|, \quad \|A\|_1 = \max_{1 \leq j \leq n} \sum_{i=1}^m |a_{ij}|.$$

Stochastic orders are denoted by O_p and o_p , while deterministic orders are O and o . We say $a \asymp b$, is $a = O(b)$ and $b = O(a)$. For matrices, \mathbf{O}_p and \mathbf{o}_p denote element-wise stochastic orders. A matrix \mathbf{A} is $\mathbf{O}_p(1)$ if all elements are $O_p(1)$, and $\mathbf{o}_p(1)$ if all elements are $o_p(1)$. The notation $O_p(a \vee b)$ denotes $O_p(\max(a, b))$ and $O_p(a \wedge b)$ denotes $O_p(\min(a, b))$. $\max_i \mathbf{A}_i$ denotes the element-wise maximum of matrices $\{\mathbf{A}_i\}_{i \in \{1, \dots, N\}}$. The abbreviation ‘w.p.’ stands for ‘with probability’ and ‘iff’ stands for if and only if.

2 The Estimator

We predict the target \mathbf{y} using a two-stage process which we call 3PRF LASSO. Stage 1 of this process is the three-pass filter by Kelly & Pruitt [2015]. The three-pass regression filter

is essentially a sequence of linear regressions aimed at consolidating information from a large set of predictors in a small set of factor(s). Once we obtain the target relevant factor(s) from the first stage, we regress each \mathbf{x}_i on them and estimate the residual(s). Thereafter, we perform a LASSO regression to extract any predictive content in these residuals for our target \mathbf{y} . Detailed procedure is outlined below.

Algorithm 1 : 3PRF-LASSO Procedure

Stage-1 (Three Pass regression Filter, 3PRF)	
Pass	Description
1.	Run time series regression of \mathbf{x}_i on \mathbf{Z} for $i = 1, \dots, N$, $x_{i,t} = \tilde{\phi}_{0,i} + \tilde{\phi}_i' \mathbf{z}_t + \hat{v}_{it}$, retain slope estimate $\tilde{\phi}_i$.
2.	Run cross-section regression of \mathbf{x}_t on $\tilde{\phi}_i$ for $t = 1, \dots, T$, $x_{i,t} = \tilde{\phi}_{0,t} + \tilde{\phi}_i' \hat{\mathbf{F}}_t + \tilde{\varepsilon}_{it}$, retain slope estimate $\hat{\mathbf{F}}_t$.
3.	Run time series regression of y_{t+h} on predictive factors $\hat{\mathbf{F}}_t$, $y_{t+h} = \hat{\beta}_0 + \hat{\beta}' \hat{\mathbf{F}}_t + \hat{u}_{t+h}$, delivers initial forecast $\hat{y}_{t+h,f} = \hat{\beta}_0 + \hat{\mathbf{F}}_t' \hat{\beta}$. Retain the residual \hat{u}_{t+h} and the initial forecast initial forecast $\hat{y}_{t+h,f}$.
Stage-2 (Three-Pass Regression Filter augmented with Lasso, 3PRF-Lasso)	
Pass	Description
4.	Run time series regression of \mathbf{x}_i on $\hat{\mathbf{F}}$ for $i = 1, \dots, N$, $x_{i,t} = \hat{\phi}_{0,i} + \hat{\phi}_i' \hat{\mathbf{F}}_t + \hat{\varepsilon}_{it}$, retain the residual $\hat{\varepsilon}_{it}$
5.	Run LASSO regression of \hat{u}_{t+h} obtained from Pass 3 in stage 1 on the estimated residuals $\hat{\varepsilon}_{it}$, $\hat{u}_{t+h} = \hat{\gamma}' \hat{\varepsilon}_t + \hat{\eta}_{t+h}$.
The final forecast is given by	
6.	$\hat{y}_{t+h} = \hat{\beta}_0 + \hat{\beta}' \hat{\mathbf{F}}_t + \hat{\gamma}' \hat{\varepsilon}_t$

The final forecast is a sum of stage 1 and stage 2 forecasts. We can rewrite the forecast as

$$\hat{\mathbf{y}} = \underbrace{\iota_T \bar{y} + \mathbf{J}_T' \hat{\mathbf{F}} \hat{\beta}}_{\hat{\mathbf{y}}_f} + \underbrace{\hat{\varepsilon}_t' \hat{\gamma}}_{\hat{\mathbf{y}}_\varepsilon},$$

where the stage 1 forecast is given by

$$\begin{aligned}\hat{\mathbf{y}}_f &= \iota_T \bar{\mathbf{y}} + \mathbf{J}_T \hat{\mathbf{F}} \hat{\boldsymbol{\beta}} \\ &= \iota_T \bar{\mathbf{y}} + \mathbf{J}_T \mathbf{X} \mathbf{W}_{XZ} (\mathbf{W}'_{XZ} \mathbf{S}_{XX} \mathbf{W}_{XZ})^{-1} \mathbf{W}'_{XZ} \mathbf{S}_{Xy},\end{aligned}$$

The estimated factor(s) are given by

$$\hat{\mathbf{F}}' = \mathbf{S}_{ZZ} (\mathbf{W}'_{XZ} \mathbf{S}_{XZ})^{-1} \mathbf{W}'_{XZ} \mathbf{X}',$$

and the estimated coefficient(s) of the factor(s) are given by

$$\hat{\boldsymbol{\beta}} = \mathbf{S}_{ZZ} \mathbf{W}_{XZ} \mathbf{S}_{XZ} (\mathbf{W}'_{XZ} \mathbf{S}_{XX} \mathbf{W}_{XZ})^{-1} \mathbf{W}'_{XZ} \mathbf{S}_{Xy}.$$

Alternatively, we can rewrite the stage-1 forecast as

$$\hat{\mathbf{y}}_f = \iota_T \bar{\mathbf{y}} + \mathbf{J}_T \mathbf{X} \hat{\boldsymbol{\alpha}},$$

where $\hat{\boldsymbol{\alpha}}$ is the implied predictive coefficient for \mathbf{X} and is given by

$$\hat{\boldsymbol{\alpha}} = \mathbf{W}_{XZ} (\mathbf{W}'_{XZ} \mathbf{S}_{XX} \mathbf{W}_{XZ})^{-1} \mathbf{W}'_{XZ} \mathbf{S}_{Xy}.$$

The procedure described above relies on the availability of suitable proxies, which can be obtained through relationships established in economic theory or constructed using the target variable in a sequential manner. Proxies constructed using \mathbf{y} are referred to as automatic proxies (auto-proxies for short). [Kelly & Pruitt \[2015\]](#) explains how such auto-proxies can always be constructed. The process to obtain L proxies is laid out below. Theorem 7 of [Kelly & Pruitt \[2015\]](#) proves that such proxies are valid; in the sense that they adhere to the assumptions of the model outlined in [Section 3](#).

Algorithm 2: Auto-Proxy Algorithm

-
-
0. Initialize $\mathbf{r}_0 = \mathbf{y}$. For $k = 1, \dots, L$ (where L is the total number of proxies):
 1. Define the k^{th} automatic proxy to be \mathbf{r}_{k-1} . Stop if $k = L$; otherwise proceed.
 2. Compute 3PRF for target \mathbf{y} using cross-section \mathbf{X} and statistical proxies 1 through k .
Denote the resulting forecast $\hat{\mathbf{y}}_k$.
 3. Calculate $\mathbf{r}_k = \mathbf{y} - \hat{\mathbf{y}}_k$, advance k , and go to step 1.
-
-

To understand the functioning of this three-pass procedure, it is instructive to look at the data generating process for the proxies.

$$\mathbf{Z} = \boldsymbol{\iota}_T \boldsymbol{\lambda}'_0 + \mathbf{F} \boldsymbol{\Lambda}' + \boldsymbol{\varepsilon} \boldsymbol{\zeta}' + \boldsymbol{\omega}. \quad (2.1)$$

Kelly & Pruitt [2015] mention that “Fluctuations in the latent factors cause the cross section of predictors to fan out and compress over time. First-stage coefficient estimates map the cross-sectional distribution of predictors to the latent factors.” This statement holds true only if the composite error term $\boldsymbol{\varepsilon} \boldsymbol{\zeta}' + \boldsymbol{\omega}$ is uncorrelated with the idiosyncratic components of \mathbf{X} . In the framework of Kelly & Pruitt [2015], $\boldsymbol{\zeta} = \mathbf{0}$, and it is assumed that $\boldsymbol{\omega}$ is uncorrelated with $\boldsymbol{\varepsilon}$, which is highly restrictive. The set of proxies typically is a small subset of the predictors or is created using the target variable (see Auto-Proxy Procedure). The assumption made by Kelly & Pruitt [2015] is akin to assuming a strict, rather than the usual ‘approximate’, factor structure among the proxies. Such a formulation lacks substantiation unless there is reason to believe that the target and the proxies are characteristically disparate from other predictors, which is typically not the case in empirical applications.

When this assumption fails, we encounter what we refer to as the ‘corrupted supervisor’ problem; the supervisor is imperfect in the sense that it cannot estimate all the loadings consistently in the first pass of the three-pass procedure. To illustrate this, consider a simplified case where there is only one factor. It can be easily verified that when $\boldsymbol{\zeta} = \mathbf{0}$ and $\boldsymbol{\omega}$ is uncorrelated with $\boldsymbol{\varepsilon}$, then, through pass 1 of stage 1, we obtain $\tilde{\phi}_i = c\phi_i + O_p(T^{-1/2})$, where c is a constant not dependent on i . This implies that pass 1 of the three-pass procedure can estimate all loadings up to a constant of proportionality. However, this convenient feature is lost when $\boldsymbol{\zeta} \neq \mathbf{0}$, since in that case, for all j such that $\zeta_j \neq 0$, we would have $\tilde{\phi}_j = c\phi_j + d_j +$

$O_p(T^{-1/2})$. This d_j term is $O_p(1)$ and arises from the correlation between $\{\varepsilon_j | \zeta_j \neq 0\}$ in the data generating process of \mathbf{Z} and predictor(s) in the set $\Delta_j = \{\mathbf{x}_i | \varepsilon_i \text{ is correlated with } \varepsilon_j\}$. Through a set of assumptions, we restrict the extent of this corruption. Once we ensure that pass-1 functions properly, “Second-stage cross-section regressions use the estimated mapping in Pass-1 to back out estimates of the factors at each point in time” as in Kelly & Pruitt [2015], enabling consistent estimation in stage-1 3PRF. stage-2 simply proceeds by using consistent estimates of the factors in stage 1.

Remark 1. *One practical issue is choosing the number of factors when we are using the auto-proxy algorithm. Kelly & Pruitt [2015] adopt a method initially presented by Krämer & Sugiyama [2011] to calculate the number of factors. We, do not delve into the question of estimating the number of factors in this paper. One may use an information criteria as mentioned or divide the data into a training and validation set and estimate the number of relevant factors using a cross validation technique. Using a single 3PRF factor is a prudent choice as highlighted in Appendix 7.2 of Kelly & Pruitt [2015]. They demonstrate that there are situations where the original data generating process (DGP) of \mathbf{y} , which involves multiple relevant factors, can be reformulated as a DGP with a single relevant factor. Moreover, in cases where a single-factor representation is not feasible, the variation in the target explained by the first estimated factor typically far exceeds that explained by the factors estimated subsequently, as demonstrated in Appendix 7.3 of Kelly & Pruitt [2015]. This is due to the fact that 3PRF estimates the rotation of underlying factors, with the first rotation explaining the maximal variation of the target.*

3 Setup

Below, we delineate our data generating process and the associated assumptions.

Assumption 1. *(Data generating Process).*

For any vector \mathbf{x} , let $x(m)$ denote the m^{th} element of \mathbf{x}

$$\begin{aligned} \mathbf{x}_t &= \phi_0 + \Phi \mathbf{F}_t + \varepsilon_t, & y_{t+h} &= \beta_0 + \beta' \mathbf{F}_t + \gamma' \varepsilon_t + \eta_{t+h}, & \mathbf{z}_t &= \lambda_0 + \Lambda \mathbf{F}_t + \zeta \varepsilon_t + \omega_t, \\ \mathbf{X} &= \iota_T \phi'_0 + \mathbf{F} \Phi' + \varepsilon, & \mathbf{y} &= \iota_T \beta_0 + \mathbf{F} \beta + \varepsilon \gamma + \eta, & \mathbf{Z} &= \iota_T \lambda'_0 + \mathbf{F} \Lambda' + \varepsilon \zeta' + \omega. \end{aligned}$$

where $\mathbf{F}_t = (f'_t, g'_t)'$, $\Phi = (\Phi_f, \Phi_g)$, $\Lambda = (\Lambda_f, \Lambda_g)$, and $\beta = (\beta'_f, \mathbf{0})'$ with $|\beta_f| > \mathbf{0}$. $K_f > 0$

is the dimension of vector \mathbf{f}_t , $K_g \geq 0$ is the dimension of vector \mathbf{g}_t , $L > 0$ is the dimension of vector \mathbf{z}_t , and $K = K_f + K_g$. $\forall j \in \{i | \gamma_i \neq 0\}$, $\beta(m) = 0 \implies \phi_j(m) = 0$.

Assumption 1 characterizes the factor structure of the predictors and the data-generating process for both the target and proxies. The target is driven by a subset of factors that drive variation in the predictors. In addition, the target is allowed to be correlated with the idiosyncratic components, a modification from Kelly & Pruitt [2015]. In the usual framework, factor(s) act as a convenient conduit relating \mathbf{X} to \mathbf{y} . This involves an implicit assumption that \mathbf{X} has no explanatory power for the target after accounting for the latent factors, which may be unrealistic in various settings. The proxies, like the target, are also driven by a subset of factor(s) and idiosyncratic components.

The idea of allowing the predictors to retain explanatory power for the target after accounting for latent factors has been explored in other studies as well. Examples include Kneip & Sarda [2011], Kapetanios & Marcellino [2010], and Fan *et al.* [2023a]. The latter two papers assume a DGP for the target, which takes the following form,

$$\begin{aligned} \mathbf{y} &= \boldsymbol{\iota}_T \beta_0^* + \mathbf{F} \boldsymbol{\beta}^* + \mathbf{X} \boldsymbol{\gamma}^* + \boldsymbol{\eta} \\ &= \boldsymbol{\iota}_T (\beta_0^* + \phi_0' \boldsymbol{\gamma}^*) + \mathbf{F} (\boldsymbol{\beta}^* + \boldsymbol{\phi}' \boldsymbol{\gamma}^*) + \boldsymbol{\varepsilon} \boldsymbol{\gamma}^* + \boldsymbol{\eta}. \end{aligned}$$

Comparing it with the DGP of \mathbf{y} given in Assumption 1, one can clearly see that, $\boldsymbol{\gamma} = \boldsymbol{\gamma}^*$ and $\boldsymbol{\beta}(m) = \boldsymbol{\beta}^*(m) + \sum_i \phi_i(m) \boldsymbol{\gamma}_i^* = 0$. We assume that $\boldsymbol{\beta}^*(m) + \sum_i \phi_i(m) \boldsymbol{\gamma}_i^* = 0$ only if $\boldsymbol{\beta}^*(m) = 0$ and $\forall j \in \{i | \gamma_i^* \neq 0\}$ we have $\phi_j(m) = 0$. We are ruling out the pathological cases where both these aforementioned quantities are not 0 but the sum $\boldsymbol{\beta}^*(m) + \sum_i \phi_i(m) \boldsymbol{\gamma}_i^* = 0$. This assumption is succinctly expressed as $\forall j \in \{i | \gamma_i \neq 0\}$, $\beta(m) = 0 \implies \phi_j(m) = 0$. This assumption allows us to consistently recover the true idiosyncratic terms in stage-2 Pass 4 for the relevant \mathbf{x}_i (i.e., $\{\mathbf{x}_i | \gamma_i \neq 0\}$) and subsequently implement pass-5 in stage 2.

Assumption 2. (*Factors, Loadings and Residuals*).

Let $M < \infty$. For any i, s, t , $0 < \psi_f \leq 1$ and $0 < \psi_g \leq 1$,

1. $\mathbb{E} \|\mathbf{F}_t\|^4 < M$, $T^{-1} \sum_{s=1}^T \mathbf{F}_s \xrightarrow[T \rightarrow \infty]{p} \boldsymbol{\mu}$ and $T^{1/2} \left(\frac{\mathbf{F}' \mathbf{J}_T \mathbf{F}}{T} - \boldsymbol{\Delta}_F \right) = \mathcal{O}_p(1)$.
2. $\mathbb{E} \|\phi_i\|^4 \leq M$. For $v = f, g$, $N^{-\psi_v} \sum_{j=1}^N \phi_{vj} \xrightarrow[N \rightarrow \infty]{p} \overline{\phi_v} < \infty$, $N^{\psi_v/2} \left(\frac{\boldsymbol{\Phi}_v' \mathbf{J}_N \boldsymbol{\Phi}_v}{N^{\psi_v}} - \mathcal{P}_v \right) = \mathcal{O}_p(1)$ and for $\psi_s = \min(\psi_f, \psi_g)$, $N^{\psi_s/2} \left(\frac{\boldsymbol{\Phi}_f' \mathbf{J}_N \boldsymbol{\Phi}_g}{N^{\psi_s}} - \mathcal{P}_{fg} \right) = \mathcal{O}_p(1)$.

$$3. \mathbb{E}(\varepsilon_{it}) = 0, \mathbb{E}\|\varepsilon_{it}\|^8 \leq M.$$

$$4. \mathbb{E}(\boldsymbol{\omega}_t) = \mathbf{0}, \mathbb{E}\|\boldsymbol{\omega}_t\|^4 \leq M, T^{-1/2} \sum_{s=1}^T \boldsymbol{\omega}_s = \mathcal{O}_p(1) \text{ and } T^{1/2} \left(\frac{\boldsymbol{\omega}' \mathbf{J}_T \boldsymbol{\omega}}{T} - \boldsymbol{\Delta}_\omega \right) = \mathcal{O}_p(1).$$

$$5. \mathbb{E}_t(\eta_{t+h}) = \mathbb{E}(\eta_{t+h} \mid y_t, F_t, y_{t-1}, F_{t-1}, \dots) = 0, \mathbb{E}(\eta_{t+h}^2) = \delta_\eta < \infty, \text{ and } \eta_{t+h} \text{ is independent of } \phi_i(m) \text{ and } \varepsilon_{i,t} \text{ for any } h > 0.$$

Assumptions 2.1-2.3 and 2.5, with $\psi_f = \psi_g = 1$, are standard in the literature, as seen in Stock & Watson [2002], Bai & Ng [2006], and Kelly & Pruitt [2015], and characterize a ‘strong factor’ model.

Recent research has extended the study of factor strength to scenarios where it is strictly less than one, particularly in the context of Principal Component (PC) factors, as explored in Freyaldenhoven [2022] and Bai & Ng [2023]. In our framework, we allow for $0 < \psi_f \leq 1$ and $0 < \psi_g \leq 1$, with ψ_f and ψ_g potentially differing. This generalizes the Three-Pass Regression Filter (3PRF) approach of Kelly & Pruitt [2015] by incorporating weak factors.

Assumption 2.4 is similar to the assumption in Kelly & Pruitt [2015] that ensures that the proxy noise is well-behaved. The fact that conditional expectation of η_{t+h} w.r.t information set in time t is 0 implies that $\beta_0 + \boldsymbol{\beta}'_f \mathbf{f}_t + \boldsymbol{\gamma}' \boldsymbol{\varepsilon}_t$ provides the optimal forecast of the target at time t . However, this forecast is infeasible as the factors and idiosyncratic components are not known.

Assumption 3. (*Dependence*).

Let $x(m)$ denote the m^{th} element of \mathbf{x} . For $M < \infty$ and any i, j, t, s, m_1, m_2 and $v = f, g$

1. Let $\mathbb{E}(\varepsilon_{it}\varepsilon_{js}) = \sigma_{ij,ts}$, $|\sigma_{ij,ts}| \leq \bar{\sigma}_{ij}$, $|\sigma_{ij,ts}| \leq \tau_{ts}$, and
 - a. $N^{-1} \sum_{i,j=1}^N \bar{\sigma}_{ij} \leq M$.
 - b. $T^{-1} \sum_{t,s=1}^T \tau_{ts} \leq M$.
 - c. $N^{-1} \sum_{i,s} |\sigma_{ii,ts}| \leq M$.
 - d. $T^{-1} \sum_{i,t} |\sigma_{ij,tt}| \leq M$.
 - e. $N^{-1} T^{-1} \sum_{i,j,t,s} |\sigma_{ij,ts}| \leq M$.
2. (a) $\mathbb{E} \left| N^{-1/2} T^{-1/2} \sum_{s=1}^T \sum_{i=1}^N [\varepsilon_{is}\varepsilon_{it} - \sigma_{ii,st}] \right|^4 \leq M$.
 (b) $\mathbb{E} \left| N^{-1/2} T^{-1/2} \sum_{s=1}^T \sum_{i=1}^N [\varepsilon_{is}\varepsilon_{js} - \sigma_{ij,ss}] \right|^4 \leq M$.
3. $\mathbb{E} \left| N^{-\psi_v/2} T^{-1/2} \sum_{t=1}^T \sum_{i=1}^N \phi_{iv}(m) [\varepsilon_{it}\varepsilon_{jt} - \sigma_{ij,tt}] \right|^2 \leq M$.⁷

⁷If weakness in loadings is induced by sparsity, i.e., the factor(s) are local, then we can use Assumption 3.3

4. $\mathbb{E} \left| T^{-1/2} \sum_{t=1}^T F_t(m_1) \omega_t(m_2) \right|^2 \leq M.$
5. $\mathbb{E} \left| T^{-1/2} \sum_{t=1}^T \omega_t(m) \varepsilon_{it} \right|^2 \leq M.$
6. $\mathbb{E} \left| T^{-1/2} \sum_{t=1}^T F_t(m) \varepsilon_{it} \right|^2 \leq M.$
7. $\mathbb{E} \left| N^{-\psi_v/2} \sum_{i=1}^N \phi_{iv}(m_1) \varepsilon_{it} \right|^2 \leq M.$

Assumption 3.1-2 allow weak cross-sectional and temporal dependence in the idiosyncratic components; these set of assumptions characterize an approximate factor model(Chamberlain & Rothschild [1983]). Essentially, we require that the idiosyncratic components lack an underlying factor structure, as the presence of such a structure would render the true factor space unidentifiable. Assumptions 3.1-3.4 with $\psi_f = \psi_g = 1$ are common in literature, see Bai [2003], Stock & Watson [2002], Kelly & Pruitt [2015] among others. Bai & Ng [2023] extends Bai [2003] to accommodate weak factors by making similar adjustments to the assumptions as we have done above.

Assumptions 3.4-3.7 are reasonable since they involve products of orthogonal series. We can specify lower-level conditions (several mixing conditions) which guarantee 3.1-3.7, but for the sake of simplicity, we instead state these high-level assumptions, as done in other papers, see Kelly & Pruitt [2015], Bai [2003] and Stock & Watson [2002] etc.

Assumption 4. (*Uncorrelated loadings and Factors*).

1. \mathcal{P}_f is positive definite and $\mathcal{P}_{fg} = 0.$
2. $\Delta_F \equiv \begin{pmatrix} \Delta_f & \Delta_{fg} \\ \Delta_{fg} & \Delta_g \end{pmatrix}$ is positive definite and $\Delta_{fg} = 0.$

We require that the relevant factors be uncorrelated with the irrelevant factors and that the associated relevant factor loadings also be uncorrelated with the irrelevant factor loadings. This condition is less stringent than the assumption in Kelly & Pruitt [2015], where all loadings are assumed to be orthogonal to each other, and all factors are also assumed to be mutually orthogonal.⁸

Assumption 5. (*Relevant Proxies*).

to prove 3.4 by slightly modifying the argument in Kelly & Pruitt [2015] Lemma 1.1 and 1.2. However, we consider a more general setting where factors(s) may not be local; instead, all loadings are weak, and hence we introduce this assumption.

⁸See Assumption 5 (Normalization) in Kelly & Pruitt [2015].

1. $\mathbf{\Lambda} = \begin{bmatrix} \mathbf{\Lambda}_f & \mathbf{0} \end{bmatrix}$.

2. $\mathbf{\Lambda}_f$ is non-singular.

Assumption 5 is borrowed from Kelly & Pruitt [2015]. We require proxies to mimic the target in terms of their dependence on factors. The assumption asserts that proxies must meet three criteria: (i) they should not load on irrelevant factors, (ii) their loadings on relevant factors should be linearly independent, and (iii) their number should match the number of relevant factors. When combined with Assumption 4, this implies that the common components of proxies span the relevant factor space and that none of the variation in proxies stems from irrelevant factors.

Assumption 6. For $v = f, g$, define $\Gamma_{N,v,T} \equiv \min(\sqrt{N^{\psi_v}}, \sqrt{T})$ and $\delta_{N,T} \equiv \min(\sqrt{N}, \sqrt{T})$.

We need the following:

$$(1) \quad \lim_{N \rightarrow \infty, T \rightarrow \infty} \frac{N^{1-\psi_f}}{\sqrt{T} \delta_{N,T}} = \max \left(\frac{N^{1-\psi_f}}{T}, \frac{N^{1/2-\psi_f}}{T^{1/2}} \right) = 0.$$

$$(2) \quad \lim_{N \rightarrow \infty, T \rightarrow \infty} \frac{N^{\psi_g-\psi_f}}{\Gamma_{N_g,T}} = \max \left(\frac{N^{\psi_f-\psi_g}}{\sqrt{T}}, N^{\psi_f-\frac{\psi_g}{2}} \right) = 0.$$

This assumption specifies the necessary growth rate of T relative to N under a weak factor structure. It is automatically satisfied when $\psi_f = \psi_g = 1$. When all factors have same strength, $\psi_f = \psi_g = \psi$, (1) implies that a small ψ necessitates a larger T relative to N for consistent estimation. This requirement embodies an implicit cost imposed by a weak factor structure. When $\psi_f \geq \psi_g$, (2) is automatically satisfied. Conversely, when $\psi_f < \psi_g$, (2) reflects the cost of having higher noise (irrelevant factors) relative to the signal (relevant factors). Furthermore, (2) imposes a limit on the weakness of the relevant factors compared to the irrelevant factors, requiring that $\psi_f > \frac{\psi_g}{2}$.

Assumption 7. (Uniform bounds).

For all m, N and T , $v = f, g$ and some positive constants r_1, \dots, r_5 ,

1. $\max_i \phi_i(m) = O_p(1)$.

2. $\max_{it} |\varepsilon_{it}| = O_p((\log N)^{r_1}) + O_p((\log T)^{r_1})$.

3. $\max_i \left| \sum_{t=1}^T \frac{1}{\sqrt{T}} \varepsilon_{it} \right| = O_p((\log N)^{r_2})$ and $\max_t \left| \sum_{i=1}^N \frac{1}{\sqrt{N}} \varepsilon_{it} \right| = O_p((\log T)^{r_2})$.

4. $\max_i \left| \frac{1}{\sqrt{T}} \sum_{t=1}^T F_t(m) \varepsilon_{it} \right| = O_p((\log N)^{r_3}).$
5. $\max_i \left| N^{-\psi_f/2} T^{-1/2} \sum_{j,t} \phi_{jf}(m) \varepsilon_{jt} \varepsilon_{it} \right| = O_p((\log N)^{r_4}).$
6. $\max_i \left| N^{-1/2} T^{-1/2} \sum_{j,t} \varepsilon_{it} \varepsilon_{jt} \right| = O_p((\log N)^{r_5}).$

We impose some high-level assumptions. We require uniform bounds on certain empirical processes to ensure that the prediction error in the first stage does not adversely affect the theoretical results in second stage LASSO regression. Such assumptions are prevalent in the literature. Specifically, [1](#) is featured in [Fan *et al.* \[2020\]](#) and [Giglio *et al.* \[2023\]](#) and references therein. In fact, [Fan *et al.* \[2020\]](#) assumes that the maxima of factors, loadings, and idiosyncratic terms do not scale with N and T and are uniformly bounded by some constant.⁹ Similarly, [Giglio *et al.* \[2023\]](#) incorporates [2](#) with $r_1 = 1/2$. The partial sums (after centering) in [4–6](#) (without taking the maximum over i) are bounded by Assumptions [3.2](#), [3.3](#), and [3.6](#). We assume that the maximum of these empirical processes scales as some power of the logarithm of N . This assumption is equivalent to imposing a uniform tail bound (see [remark 2](#)) on the distribution of these partial sums.

Remark 2. *The scaling properties outlined in [7](#) are often associated with Weibull distributions, which are widely employed in economics. Their flexibility and ability to capture various shapes of distributions make them a general and versatile assumption in economic analyses. A more general assumption could be to impose moment bounds on the random variables and scaled partial sums in [7](#). For a random variable \mathcal{X}_i , where $i \in \{1, \dots, N\}$, if $\mathbb{E}(\mathcal{X}_i^k) < M$ for some finite k , then by Markov Inequality we have*

$$\mathbb{P}(\mathcal{X}_i > N^{1/k}) < \frac{\mathbb{E}(\mathcal{X}_i^k)}{(N^{1/k})^k} \leq \frac{M}{N}.$$

Hence, $\max_i \mathbb{P}(\mathcal{X}_i > N^{1/k}) \leq \frac{MN}{N} \leq M$; the highest ordered statistic of \mathcal{X} scales with the rate at most $N^{1/k}$. Therefore, we can instead state Assumption [7](#) by assuming the existence of a sufficiently large k that allows the theoretical properties of second-stage LASSO as stated in [Theorem 5](#) to hold.

Assumption 8. *(Weak cross sectional dependence)*

For each i , let $\Delta_{i,\varepsilon} \equiv \{j | \mathbb{E} \left| T^{-1/2} \sum_{t=1}^T \varepsilon_{it} \varepsilon_{jt} \right|^2 \leq M < \infty\}$. Then $N - |\Delta_{i,\varepsilon}| \leq M_2 < \infty$.

⁹See Assumption 4.6 regarding \mathbf{W}_{\max} in [Fan *et al.* \[2020\]](#).

Assumption 8 strengthens Assumption 3 by imposing a truncated form of cross-sectional dependence. Such a truncation in temporal dependence is commonly assumed in the literature; for instance, see Gonçalves *et al.* [2017]. A non-zero ζ introduces ‘corruption’ in the supervisor, which necessitates assuming weaker dependence in the idiosyncratic terms to enable consistent estimation.

Assumption 9. (*‘Relevant’ idiosyncratic terms and mimicking proxies*).

Let $S \equiv \{i | \gamma_i \neq 0\}$. $|S| \leq M < \infty$.

$\gamma_i = 0$ iff $\zeta'_i = 0$, where ζ'_i denotes the i^{th} row of matrix ζ' .

We require the set of ‘relevant idiosyncratic’ terms to be finite. If this set were allowed to grow in size, we would need to adjust the rates in various ensuing Theorems. The dependence of the target (and thereby proxies) on idiosyncratic terms leads to noisier estimation in stage 1 of the 3PRF-LASSO Procedure. If many idiosyncratic terms have explanatory power for \mathbf{y} , the extent of corruption in the stage-1 Pass-1 (supervising step) is greater. The assumption that $\gamma_i = 0$ iff $\zeta'_i = 0$ can be relaxed. We only require that $|\{i | \zeta'_i \neq 0\}| < \infty$ to establish our theoretical results. However, since \mathbf{Z} is used as a proxy for \mathbf{y} , it is reasonable to assume that their data-generating processes are similar.

Remark 3. *The dependence of the target on idiosyncratic terms can be ‘dense’ in the sense that a lot of idiosyncratic terms have non-0 small coefficients, see He [2023]. In such cases, as shown in their paper, ridge regression is asymptotically efficient in capturing both factor and idiosyncratic information among the entire class of spectral regularized estimators. Our model, unlike their paper, assumes that the dependence of the target on idiosyncratic terms is sparse, more akin to the setting in Fan et al. [2020] and Kneip & Sarda [2011].*

Assumption 10. (*For stage- 2 LASSO Regression*)

(a) With r_1, \dots, r_5 defined in Assumption 7,

$$(i) \text{ For } r \in \{r_2, \dots, r_5\}, \quad \frac{(\log N)^r}{\sqrt{T}} = O(1).$$

$$(ii) \quad \frac{N^{1-\psi_f}}{\sqrt{T}} [(\log N)^{r_1} + (\log T)^{r_1}] = O(1).$$

(b) \exists a large enough constant $\kappa > 0$ s.t $\forall i \in \{1, \dots, N\}$, and $\forall T$, we have,

$$\mathbb{P} \left(\frac{|\sum_{t=1}^T \varepsilon_{it} \eta_{t+h}|}{\sqrt{T}} > s \right) \leq \exp \left(\frac{-s^2}{\kappa} \right).$$

(c) (Compatibility condition) Define $\Delta_{\varepsilon, g} := (\varepsilon + \mathbf{J}_T \mathbf{g} \Phi_g')' (\varepsilon + \mathbf{J}_T \mathbf{g} \Phi_g') / T$. For the $N \times N$ matrix $\Delta_{\varepsilon, g}$, we say that, w.r.t $\Delta_{\varepsilon, g}$, the compatibility condition is met for some set $A \subset \{1, \dots, N\}$, if for some compatibility constant $\nu > 0$, and for all $N \times 1$ vectors Θ satisfying $\|\Theta_{A^c}\|_1 \leq 3 \|\Theta_A\|_1$, it holds that

$$\|\Theta_A\|_1^2 < (\Theta' \Delta_{\varepsilon, g} \Theta) |A| / \nu^2.$$

We assume that, w.p approaching one, the compatibility condition is met for set S defined in Assumption 9, w.r.t $\Delta_{\varepsilon, g}$ and the associated compatibility constant is ν_0 .

Assumption 10(a) is required to bound the impact of estimation errors in stage 1 on stage 2, as generated regressors are used in stage 2.

Assumption 10 (b) is a common assumption in LASSO literature, as seen in Bühlmann & Van De Geer [2011]. This assumption essentially states that the relevant idiosyncratic components are not highly correlated.

4 Theoretical Results

We present each of the Theorems 1-4 in two parts, labeled as parts a and b. The first part accommodates the idea of weak factor(s), while the subsequent part (b) focuses on cases where idiosyncratic terms have predictive content for the target. We, therefore, cater to diverse readerships; certain readers may find one part more relevant than the other, while some may be interested in both.

Asymptotic results throughout the paper are based on simultaneous N and T limits, as in Bai [2003] and Kelly & Pruitt [2015]. As explained in Bai [2003], a simultaneous limit implies the existence of coinciding sequential and path-wise limits, but not vice-versa. Proofs for all the Theorems are provided in the Online Appendix.

Define $\Xi_{NT}^{-1} \equiv \max \left(T^{-1/2}, N^{-\psi_f/2}, \frac{N^{\psi_g - \psi_f}}{\Gamma_{N_g T}} \right) = \max \left(T^{-1/2}, N^{-\psi_f/2}, N^{-\psi_f + \psi_g/2}, \frac{N^{\psi_g - \psi_f}}{\sqrt{T}} \right)$, where the equality follows from substituting the value of $\Gamma_{N_g T}$ as defined in 6.

Theorem 1. (a) Let Assumptions 1-6 hold and $\gamma = 0$ and $\zeta = 0$. Additionally, if $\frac{N^{1-\psi_f}}{\sqrt{T}} = O(1)$, then we have,

$$\hat{y}_{t+h,f} - \mathbb{E}_t y_{t+h} = O_p(\Xi_{NT}^{-1}).$$

(b) Let Assumptions 1-6 and 8-9 hold, $\gamma \neq 0$ and $\zeta \neq 0$. Furthermore, $\frac{N^{1-\psi_f}}{\sqrt{T}} = O(1)$ and $\frac{T}{N} = O(1)$, then

$$\hat{y}_{t+h,f} - \mathbb{E}(y_{t+h} | \mathbf{F}_t) = O_p(\Xi_{NT}^{-1}).$$

Theorem 1 (a) specifies the rate of convergence of first stage forecast when $\gamma = 0$ and $\zeta = 0$ but $0 < \psi_f \leq 1$ and $0 < \psi_g \leq 1$, hence generalizing Kelly & Pruitt [2015] by accommodating weak factor(s). When $\psi_f = \psi_g = 1$, the rate is $\delta_{N,T}^{-1}$ ($\delta_{N,T} \equiv \min(\sqrt{N}, \sqrt{T})$).

Remark 4. If factor(s) are strong, Theorem 1(a) would imply that $\hat{y}_{t+h,f} - \mathbb{E}_t y_{t+h} = O_p(\delta_{NT}^{-1})$. This is different from the result in Kelly & Pruitt [2015] where the rate is $O_p(T^{-1/2})$, (see Theorem 4 in their paper). Their proof follows two steps. First they show that $\hat{y}_{t+h} - \tilde{y}_{t+h} = O_p(T^{-1/2})$ and then they argue that $\sqrt{T}\tilde{y}_{t+h} \xrightarrow{T, N \rightarrow \infty} \mathbb{E}_t y_{t+h}$. Since \tilde{y}_{t+h} is $O_p(1)$, $\sqrt{T}\tilde{y}_{t+h}$ would diverge to infinity and their statement would be false. If they erroneously wrote this and instead wanted to imply that $\sqrt{T}(\tilde{y}_{t+h} - \mathbb{E}_t y_{t+h}) \xrightarrow{T, N \rightarrow \infty} 0$, then, again this statement is false because $\tilde{y}_{t+h} - \mathbb{E}_t y_{t+h}$ has random elements which converge to 0 at a rate which is $O_p(N^{-1/2}) + O_p(T^{-1/2}) = O_p(\delta_{NT}^{-1})$.

Theorem 1 (b) establishes that the stage-1 forecast converges to the conditional expectation of the target w.r.t true relevant factors. Unlike Theorem 1 (a), this factor-based forecast is no longer optimal because γ is allowed to take a value different from 0, indicating that the idiosyncratic components contain predictive information for the target. This predictive content in idiosyncratic components is harnessed in subsequent stage-2. Theorem 1 (b) generalizes Kelly & Pruitt [2015] along 2 dimensions, i.e., accommodating weak factors and abstracting away from the assumption that $y_{t+h} - \mathbb{E}(y_{t+h} | \mathbf{F}_t)$ has a conditional expectation of zero w.r.t. information set in period t .

Theorem 2. Let $\hat{\alpha}_i$ denote the i^{th} element of $\hat{\alpha}$. If Assumptions 1-6 hold, $\gamma = 0$ and $\zeta = 0$.

If $\mathcal{P}_f = \mathbb{I}$, Then for any i ,

$$N^{\psi_f} \hat{\alpha}_i \xrightarrow[T, N \rightarrow \infty]{p} \left(\phi_{if} - N^{\psi_f-1} \bar{\phi}_f \right)' \beta_f.$$

Theorem 2 establishes consistency of the implied predictive coefficient $\hat{\alpha}$ in a scenario with possibly weak factors. This generalizes Theorem 2 of Kelly & Pruitt [2015], where this result is stated for $\psi_f = \psi_g = 1$. As argued in Kelly & Pruitt [2015], as N grows, the predictive information in \mathbf{f} is spread across a larger number of predictors so each predictor's contribution approaches zero at the rate of $\frac{1}{N}$. That is the case when the number of predictors which load on the factors is proportionate to N , i.e., strong factor(s). When the factor(s) are weak, they may either be local or have uniformly weak loadings or an amalgam thereof. If the factor(s) are not pervasive, the predictive information contained within the vector \mathbf{f} is dispersed across a few variables. The standardization term N^{ψ_f} illustrates that the predictive information is distributed across a subset of predictors; where the size of this subset is proportional to N^{ψ_f} . Hence, the contribution of each predictor goes to 0 at a slower rate compared to pervasive factors. When the factor(s) are pervasive but loadings are weak, in the sense that $\phi_{if} = c_n \tilde{\phi}_{if}$, where $\tilde{\phi}_{if}$ is a constant (not dependent on N), then Assumption 2.2, would imply that $c_n = O(N^{\psi_f-1})$, which would imply that $N \hat{\alpha}_i \xrightarrow[T, N \rightarrow \infty]{p} \left(\tilde{\phi}_{if} - \bar{\tilde{\phi}}_f \right)' \beta_f$. Consequently, when factors are pervasive but all loadings are weak (local to zero), the predictive information in \mathbf{f} is distributed across all predictors, and the relative contribution of each predictor diminishes at a rate of $\frac{1}{N}$, similar to the scenario with strong factor(s).

Theorem 3. (a) Let Assumptions 1-6 hold and $\gamma = 0$ and $\zeta = 0$. Additionally, if $\frac{N^{1-\psi_f}}{\sqrt{T}} = O(1)$, then we have,

$$\hat{\beta} - \mathbf{G}_\beta \beta_f = O_p(\Xi_{NT}^{-1}).$$

(b) Let Assumptions 1-6 and 8-9 hold, $\gamma \neq 0$ and $\zeta \neq 0$. Furthermore, $\frac{N^{1-\psi_f}}{\sqrt{T}} = O(1)$ and $\frac{T}{N} = O(1)$, then,

$$\hat{\beta} - \mathbf{G}_\beta \beta_f = O_p(\Xi_{NT}^{-1}).$$

\mathbf{G}_β is defined in the Appendix.

Theorem 3 (a) specifies the convergence rate of the vector of predictive coefficient(s) of

the factor(s), i.e., $\hat{\beta}$ to a rotated version of the true coefficient vector β . This generalizes Theorem 5 of Kelly & Pruitt [2015] by accommodating weak factor(s). Just like Theorem 1 (a), when $\psi_f = \psi_g = 1$, the rate is $\delta_{N,T}^{-1}$, which is dissimilar to the \sqrt{T} rate specified in Kelly & Pruitt [2015]. This difference stems from the definition of rotation matrix \mathbf{G}_β , see Remark 5.

Theorem 3 (b) extends the scope of Theorem 3 (a) by allowing a more general DGP where idiosyncratic elements possess predictive capabilities for the target.

Theorem 4. (a) Let Assumptions 1-6 hold and $\gamma = 0$ and $\zeta = 0$. Additionally, if $\frac{N^{1-\psi_f}}{\sqrt{T}} = O(1)$, we have,

$$\hat{\mathbf{F}}_t - (\mathbf{H}_0 + \mathbf{H}_f \mathbf{f}_t) = O_p(\Xi_{NT}^{-1}).$$

(b) Let Assumptions 1-6 and 8-9 hold, $\gamma \neq 0$ and $\zeta \neq 0$. Furthermore, $\frac{N^{1-\psi_f}}{\sqrt{T}} = O(1)$ and $\frac{T}{N} = O(1)$, we have,

$$\hat{\mathbf{F}}_t - (\mathbf{H}_0 + \mathbf{H}_f \mathbf{f}_t) = O_p(\Xi_{NT}^{-1}).$$

\mathbf{H}_f and \mathbf{H}_0 are defined in the Appendix and $\mathbf{H}_f' \mathbf{G}_\beta = \mathbb{I}$.

Similar to the aforementioned Theorems, both Theorem 4 (a) and Theorem 4 (b) extend the findings of Theorem 6 in Kelly & Pruitt [2015] by accommodating weak factor(s) and permitting idiosyncratic terms to have predictive information for the target variable.

Theorem 4 (a) and (b) establish the convergence and the corresponding rate of the estimated factor(s) to a rotation of the true relevant factor(s). Our convergence result diverges from the one presented in Kelly & Pruitt [2015]. They demonstrate the convergence of $\hat{\mathbf{F}}_t$ to a vector $\mathbf{H}\mathbf{F}_t$ ($\mathbf{H} \neq \mathbf{H}_f$) at a \sqrt{N} rate. However, the matrix \mathbf{H} , as defined in their paper, does not satisfy certain desirable properties, which we highlight in Remark 5.

Remark 5. As highlighted in Bai & Ng [2006] and also emphasized in Kelly & Pruitt [2015], the presence of matrices \mathbf{H}_f and \mathbf{G}_β in Theorem 3 and Theorem 4 stems from our estimation of a vector space. These Theorems “pertain to the difference between $[\hat{\mathbf{F}}_t/\hat{\beta}]$ and the space spanned by $[\mathbf{F}_t/\beta]$ ”. The product $\mathbf{H}_f' \mathbf{G}_\beta$ equals an identity matrix, thereby nullifying the rotations in the predictive coefficients and relevant factors and preserving the direction spanned by $\beta' \mathbf{F}_t$. However, this characteristic is absent in Theorems 5 and 6 of

Kelly & Pruitt [2015]. The matrices \mathbf{H} and \mathbf{G}_β as defined in their paper do not necessarily yield a product that equals an identity matrix.

Theorem 5. *Let the regularization parameter in stage-2 Pass 5 regression be given by $\lambda := 2\frac{\sqrt{c + \kappa \log N}}{\Xi_{NT}}$, $c > 0$ and κ is defined in Assumption 10. Then, if Assumptions 1-10 hold, w.p. at least $1 - (\exp[-\frac{c}{\kappa}] + o(1))$, we have,*

$$\frac{1}{T} \|\hat{\boldsymbol{\varepsilon}}\hat{\boldsymbol{\gamma}} - \boldsymbol{\varepsilon}\boldsymbol{\gamma}\|_2 = O_p\left(\frac{\sqrt{\log N}}{\Xi_{NT}}\right).$$

Corollary 5.1. *From Theorem 5 and Theorem 1(b), it follows that*

$$\frac{1}{T} \|\hat{\mathbf{y}} - \mathbb{E}(\mathbf{y}|\mathbf{F}, \boldsymbol{\varepsilon})\|_2 = O_p\left(\frac{\sqrt{\log N}}{\Xi_{NT}}\right).$$

Theorem 5 establishes the rate at which the average prediction error of stage-2 LASSO regression converges to 0. The rate $\frac{\sqrt{\log N}}{\Xi_{NT}}$, in general, is different from $\sqrt{\frac{\log N}{T}}$, which represents the optimal convergence rate for a high-dimensional M estimator, as indicated in Bickel *et al.* [2009]. This slower convergence rate is induced by the complexities associated with the generated regressor problem. To mitigate the maximum estimation error (across i) when generating the idiosyncratic components, it becomes imperative to adjust the rate at which the regularization parameter asymptotically converges to zero. This necessitated adjustment leads to a more gradual rate of convergence.

4.1 Discussion and Comparison with Principal component regression

Given the theorems we have derived, we can now discuss the theoretical advantages that the 3PRF, and by extension Partial Least Squares (PLS), which is equivalent to auto-proxy 3PRF, offers over PCR. If $N^{\psi_f} = O(T)$, an advantage arises when relevant factors are stronger than irrelevant factors, i.e., $\psi_f > \psi_g$.¹⁰

To see this, consider a PCR model that uses the first K principal components, where K is equal to the number of factors, as regressors. From the discussion in Section 2.2 of Bai &

¹⁰The condition $N_f^\psi = O(T)$ is assumed to show the impact of factor convergence rates; we avoid allowing T to determine the rates, as this would trivially render both regressions with an equivalent rate.

Ng [2006], leading up to their Theorem 3, one can deduce the following:

$$\hat{y}_{t+h}^{PCR} - \mathbb{E}_t y_{t+h} = \left(\hat{\beta}^{PCR} - \beta' \mathbf{H}^{-1} \right) \hat{\mathbf{F}}_t^{PC} + \beta' \mathbf{H}^{-1} \left(\hat{\mathbf{F}}_t^{PC} - \mathbf{H} \mathbf{F}_t \right), \quad (4.1)$$

where:

- \hat{y}_{t+h}^{PCR} is the predicted value of the target at time $t+h$, formed using predictors available at time t via PCR.
- $\mathbb{E}_t y_{t+h}$ denotes the conditional expectation of the target variable at $t+h$ given the information set at t .
- \mathbf{H} is an invertible rotation matrix.
- $\hat{\mathbf{F}}_t^{PC}$ represents the estimated factors obtained as the leading K principal components.

The convergence of PCR prediction to $\mathbb{E}_t y_{t+h}$ depends on two main components:

1. The convergence of $\hat{\beta}^{PCR}$ to a rotated version of the true coefficient vector β .
2. The convergence of $\hat{\mathbf{F}}_t^{PC}$ to a rotated version of the true factors \mathbf{F}_t .

Adapting the results of Lemma 4 from Bai & Ng [2023] to the case of heterogeneous factor strengths, if $\sqrt{T}/N^{\psi_g} = o(1)$, the first term in Equation (4.1) converges to zero at a rate of \sqrt{T} . For the second term, the convergence rate depends on the elements of $\hat{\mathbf{F}}_t^{PC} - \mathbf{H} \mathbf{F}_t$ and the structure of $\beta' \mathbf{H}^{-1}$.

Even if β contains zero elements (for irrelevant factors), the rotation matrix \mathbf{H} generally leads to $\beta' \mathbf{H}^{-1}$ having non zero elements, in general. Although the components of $\beta' \mathbf{H}^{-1}$ corresponding to zero entries in β may converge to zero under specific settings, this convergence occurs more slowly than the convergence of the estimated factors to a rotated version of the true factors.

To illustrate, consider a case with two factors, F_{1t} and F_{2t} , where only the first factor is relevant to the target variable (i.e., $\beta = (\beta_1, 0)'$). If \mathbf{H} were the identity matrix, the convergence of the second term in (4.1) would depend on how fast \hat{F}_{1t}^{PC} , the first estimated factor, converges to F_{1t} .

It has been established that, under certain conditions—more restrictive than those considered in this paper—the rotation matrix \mathbf{H} converges to the identity matrix.¹¹ However, this convergence occurs at a slower rate compared to the rate at which the estimated factors converge to the rotated versions of the true factors (see Lemma 3 in Freyaldenhoven [2022]). Consequently, the convergence of the second term in Equation (4.1) is determined by the rate at which the elements of the vector $\hat{\mathbf{F}}_t^{PC}$ converge to a rotated version of \mathbf{F}_t and this rate is determined by the slowest converging element within $\hat{\mathbf{F}}_t^{PC}$. In our simplified two factor setting, if the irrelevant factor is weaker, then from Proposition 7 of Bai & Ng [2023] we have $\hat{\mathbf{F}}_t^{PC} - \mathbf{H}\mathbf{F}_t = O_p(N^{-\psi_g/2})$, and hence the convergence rate of PCR, which is determined by the two terms in Equation 4.1, and would be equal to $\min(N^{\psi_g/2}, T^{1/2}) = N^{\psi_g/2}$ as $N^{\psi_g} = o(N^{\psi_f}) = O(T)$.

One may, however, wonder what would happen if we included only the leading K_f principal components as regressors instead of all. Intuitively, this might seem advantageous, as the factors estimated using the leading K_f principal components of \mathbf{X} are expected to converge to the strongest K_f factors. These strongest factors correspond to the relevant factors when $\psi_f > \psi_g$. Thus, it might seem that using only the first K_f principal components could result in faster convergence of PCR. However, this is not the case. The estimated factors obtained via the principal component method using the first K_f principal components converge to a rotated version of the true factors, not the true factors themselves. Consequently, unless the rotation matrix converges to the identity matrix, the leading K_f principal components will provide a noisy estimate of the relevant factors. Furthermore, the convergence of the rotation matrix to the identity matrix occurs at a slow rate, limiting the potential benefits of using only the leading K_f principal components in PCR.

To make things clear, once again, consider a case with two factors: one relevant and one irrelevant, and let $\psi_f > \psi_g$. Then, according to Bai & Ng [2023], the PC estimate of the leading factor, i.e., \hat{F}_{1t}^{PC} , converges to hF_t where $h = [h_1, h_2]$. For \hat{F}_{1t} to serve as a reliable predictor, we need h_2 to converge to zero; otherwise, \hat{F}_{1t}^{PC} would represent a linear combination of relevant and irrelevant factors, not the relevant factor alone, leading to the

¹¹See Assumptions 1(b) and 1(c) in Freyaldenhoven [2022], which are substantially more restrictive than Assumption 4 imposed in our paper regarding the covariance structure of factors. Our assumptions are placed on the population covariance matrices, whereas Freyaldenhoven [2022] requires certain assumptions to hold for sample covariance matrices. Additionally, Freyaldenhoven [2022] imposes the restrictive condition that $\Phi'\Phi$ (without any normalization) is diagonal, which is a much stronger requirement. Despite these more restrictive assumptions, we compare our results to their setting and demonstrate better properties.

inconsistency of PCR (which uses only the leading principal component). Under Assumption 1 of Freyaldenhoven [2022], which is more restrictive than the assumptions in our paper, along with additional assumptions that are comparable to those we impose, we can apply Theorem 2 of Freyaldenhoven [2022] to deduce:

$$\hat{F}_{1t}^{PC} - F_{1t} = O_p\left(N^{-\frac{\psi_f}{4}}\right) + O_p\left(N^{\frac{1}{2}-\psi_f}\right) + O_p\left(N^{1-2\psi_f}\right).$$

This follows since, one can derive the following using Lemma 3 of Freyaldenhoven [2022]:

$$h - [1, 0] = O_p\left(N^{-\frac{\psi_f}{4}}\right) + O_p\left(N^{\frac{1}{2}-\psi_f}\right),$$

and $\hat{F}_{1t}^{PC} - hF_{1t} = O_p(1 - 2\psi_f) + O_p(-\psi_f/2)$. Therefore, if we use the leading Principal component in this simplified two-factor case (with a strong relevant factor and a weak irrelevant factor), our convergence rate cannot exceed $N^{\psi_f/4}$, which is much slower than $N^{\psi_f/2}$. Hence, when comparing PCR and 3PRF in a case with strong relevant factors, we restrict our attention to cases where PCR includes all factors rather than just the leading eigenvectors.

3PRF performs sub-optimally when irrelevant factors are stronger than relevant factors. In such cases, as can be inferred from Proposition 7 of Bai & Ng [2023], PCR's convergence rate to the infeasible best forecast will be $\min(N^{\psi_f/2}, T^{1/2})$, whereas for 3PRF it is strictly slower, as can be seen in Theorem 1. However, this scenario is improbable, as the predictors are typically driven by multiple irrelevant factors, with at least some of these factors being probably weaker than the relevant factors. This is discussed further in Remark 6.

Comparison of 3PRF and PCR under Different Factor Strengths	
Case	Performance Outcome
$\psi_f > \psi_g$	3PRF superior (faster convergence rate)
$\psi_f = \psi_g$	PCR and 3PRF converge at the same rate.
$\psi_f < \psi_g < 2\psi_f$	PCR converges faster, 3PRF less effective.
$\psi_g \geq 2\psi_f$	3PRF is inconsistent

Remark 6. *Introducing weaker irrelevant factors alongside stronger ones does not alter the theoretical properties of 3PRF; the strength of the strongest irrelevant factor determines its convergence rate. In contrast, the theoretical properties of PCR are affected by variations in the strength of irrelevant factors. PCR requires the inclusion of all estimated factors*

Figure 1: Convergence rate based on Factor strength. (Drawn for the case when $N \asymp T$). Point **D** at $(1, 1)$ represents full strength of both relevant and irrelevant factors as in [Kelly & Pruitt \[2015\]](#). Region **A** (Green) is where relevant factors are relatively stronger and determine convergence rates. 3PRF converges faster compared to PCR in this region. Along the line $\psi_f = \psi_g$, the convergence rates for PCR and 3PRF are the same. Region **B** (Yellow) is where weak factor strength dampens convergence rate but consistency is preserved. 3PRF is inferior to PCR in this region. Region **C** (Red) is where 3PRF is inconsistent.

as regressors, as omitting even a subset introduces issues due to rotational indeterminacy. This indeterminacy arises because PCR estimates factors as linear combinations of the true underlying factors, making it difficult to distinguish relevant factors from irrelevant ones at a sufficiently fast rate. As a result, the leading principal components (equal to the number of factors driving \mathbf{X}) must be included as regressors in PCR.

If weaker estimated factors are excluded, the noise in the rotation matrix can prevent PCR from converging at a fast enough rate. Including all PC estimated factors resolves this issue but results in slower convergence compared to 3PRF, as the weakest irrelevant factor then determines the rate of convergence in PCR. Therefore, while 3PRF's convergence rate is robust to variations in the strength of irrelevant factors—being determined by the strongest irrelevant factor—PCR's performance deteriorates when there are weaker irrelevant factors, as all such factors must be estimated and included in the predictive regression. When irrelevant factors vary in strength, with some being stronger and others weaker than the relevant

factors, the comparison between 3PRF and PCR becomes less clear; One must evaluate the trade-off between excluding weaker estimated factors, which can lead to issues arising from rotational indeterminacy, and including them, which may introduce problems due to their estimates being very noisy.

5 Simulation Analysis

To evaluate the performance of our estimator in finite samples, we undertake Monte Carlo experiments. The data is generated based on Assumption 1. We explore scenarios where $K_f = 1$ and $K_g = k$, with k taking values of either 4 or 5. The relevant and irrelevant factors are generated as follows: we begin by drawing the first observation from a $N(0, 1)$ distribution, and then draw subsequent observations as $\tilde{f}_t = \rho_f \tilde{f}_{t-1} + u_{f,t}$ and $\tilde{\mathbf{g}}_t = \rho_g \tilde{\mathbf{g}}_{t-1} + \mathbf{u}_{g,t}$ with $u_{f,t} \sim \text{IIN}(0, 1)$ and $\mathbf{u}_{g,t} \sim \text{IIN}(0, \mathbf{\Sigma}_g)$, $u_{f,t}$ and $\mathbf{u}_{g,t}$ are uncorrelated and $\mathbf{\Sigma}_g$ is an identity matrix of order k , which is either 4 or 5. We divide each factor by its standard deviation to obtain \mathbf{f} and \mathbf{g} . The parameters ρ_f and ρ_g dictate the serial correlation among factors, and they take values of 0, 0.3, or 0.9 in our setup, similar to Kelly & Pruitt [2015]. The idiosyncratic elements are generated as, $\varepsilon_{i,t} = a\varepsilon_{i,t-1} + \tilde{\varepsilon}_{i,t}$. $\tilde{\varepsilon}_{i,t} = (1 + d^2)v_{i,t} + dv_{i-1,t} + dv_{i+1,t}$ where $v_{i,t}$ is standard normal. The parameter a controls their serial correlation and takes values 0, 0.3 and 0.9 whereas d , which governs the strength of cross-sectional correlation takes values of 0 or 1. For each predictor \mathbf{x}_i , the loading on the relevant factor is drawn from an independent and identically distributed (iid) standard normal distribution, divided by $N^{1-\psi_f}$. Similarly, for each predictor, loadings on the irrelevant factors are drawn independently from a standard normal distribution, divided by $N^{1-\psi_g}$. Here, ψ_f represents the strength of the relevant factor, while ψ_g denotes the strength of all irrelevant factors. ψ_f and ψ_g take the values 0.7 or 1. For the set $\{i | \gamma_i \neq 0\}$, we make $\phi_{ig} = \mathbf{0}$, in line with Assumption 1. The target variable is generated as $y_{t+1} = f_t + \alpha \gamma' \varepsilon_t + \eta_{t+1}$, where $\eta_{t+1} \sim \text{IIN}(0, 1)$, and $\gamma = (0, 1, 1, 1, 1, \mathbf{0}_{N-5})'$. We set $\alpha = 0.3$ when $d = 1$ and $\alpha = 0.375$ when $d = 0$, ensuring that the explained variation by the factors and idiosyncratic elements remains within a narrow band. For our simulations, we use auto-proxy(\mathbf{y}).

We compare the out-of-sample performance of four methods: Principal Component Regression (as described in Stock & Watson [2002]), Three-Pass Regression Filter by Kelly & Pruitt [2015], Least absolute shrinkage and selection operator (LASSO) by Tibshirani [1996],

PCR-LASSO, and 3PRF-LASSO (our method). The PCR-LASSO method is a two-stage procedure: initially, a regression of the target is performed on the leading principal components (similar to [Stock & Watson \[2002\]](#)), followed by regressing the residuals from the initial regression on the idiosyncratic components. This process resembles our method, with the key distinction being that the factors and idiosyncratic components are generated using an unsupervised technique, i.e., Principal Components. The hyper-parameter tuning for the LASSO regressions in our simulations is performed using 10-fold cross-validation, following the approach in [Fan *et al.* \[2020\]](#). The column labeled ‘Oracle’ displays the average in-sample R-square value (across repeated samples) derived from the infeasible regression of \mathbf{y} on \mathbf{f} and the ‘relevant’ idiosyncratic elements, i.e., $\{\epsilon_i | \gamma_i \neq 0\}$. The following five columns report the average (across repeated samples) out-of-sample R-square values for the 5 aforementioned methods.

We consider 100 repeated samples. To compute the out-of-sample R-squared values, we partition the sample into two halves: a training window and a testing window, each comprising 100 observations. We use a fixed estimation window. All regression parameters, factors, and loadings are estimated using the in-sample data. Since out-of-sample factors are unknown, for each OOS period t_o , we regress \mathbf{x}_{t_o} on the in-sample estimated factor loadings to obtain estimated OOS factor(s) for period t_o . Therefore, no out-of-sample information is utilized in the estimation process.

The simulation results in [Table 1-4](#) show that, for a given strength of irrelevant factors, performance of all methods, improves as the strength of the relevant factors increases. Conversely, all methods, perform poorly when the strength of irrelevant factors increases for a fixed strength of relevant factors. This outcome is anticipated, as higher factor strength enhances the signal-to-noise ratio in all predictors, positively impacting these methods. However, when the strength of the relevant factor diminishes relative to irrelevant factors, the 3PRF and 3PRF-LASSO methods perform the poorest. This result is consistent with expectations, as the 3PRF is a supervised method and thus more sensitive to variations explained by relevant factors compared to alternative approaches. The opposite holds true when the strength of irrelevant factors decreases relative to relevant factors.

When comparing PCR and 3PRF, we note that 3PRF generally outperforms PCR, in the majority of cases, except when irrelevant factors are stronger than relevant factors. Hence,

even when idiosyncratic terms have predictive power for the target, 3PRF is able to perform well, indicating that the ‘corruption’ in the 3PRF procedure as discussed in 2 does not affect the performance too much. Therefore, 3PRF procedure is robust to minor perturbations in the Data Generating process of the auto-proxy, in terms of estimating the relevant factors.

The simulations also reveal that in the majority of cases, 3PRF and PCR are outperformed by either LASSO, 3PRF-LASSO or PCR-LASSO. This outcome is expected, as the former two techniques do not leverage the predictive power of idiosyncratic elements. When comparing 3PRF-LASSO with PCR-LASSO, we observe that 3PRF-Lasso outperforms the latter in majority of cases. The differential in performance of 3PRF-LASSO and PCR-LASSO is higher when $k_g = 5$ compared to case when $k_g = 4$, as can be seen by comparing Tables 1 and 5.¹² Tables 2 and 3 show that when relevant factors are relatively weak, 3PRF-LASSO has poor performance, but when relevant factors are relatively strong, 3PRF-LASSO performs the best. In most cases, the closest competitor of 3PRF-LASSO is LASSO, not PCR-LASSO. This implies that augmenting the factor based prediction model with an additional LASSO step is more effective when factors are estimated using 3PRF compared to the case when they are estimated as leading Principal components. This is because 3PRF, being a supervised technique leads to better estimation in the first stage, i.e., estimating the relevant factors, and the effect of this better estimation percolates into the second stage where we deal with generated regressors.

When comparing LASSO with 3PRF-LASSO, we observe that 3PRF-LASSO outperforms LASSO when relevant factors are relatively stronger than irrelevant ones. Conversely, when relevant factors are weaker relative to the irrelevant factors, LASSO shows better performance. This result is intuitive, as stronger relevant factors lead to faster-converging estimates in the first stage, which subsequently enhance the second-stage estimation.

When the training sample size $T = 100$ is half of the cross-sectional size $N = 200$, 3PRF-LASSO has a much superior performance compared to PCR-LASSO. It outperforms all other methods in every case, with the exception of LASSO, as shown in Table 6. Although 3PRF-LASSO generally outperforms LASSO in many instances, it does not consistently do so across all cases.¹³ Its superiority relative to PCR and 3PRF is understandable, as mentioned earlier

¹²The results in reported in this paper examine the effect of increasing irrelevant factors with $T = 100$, $N = 100$, and $\psi_g = \psi_f = 1$. Additional simulations in the Online Appendix show that this finding is consistent across different sample sizes and factor strengths.

¹³In this paper, we report results for $N = 200$ and $T = 100$ for all five methods with $k_g = 4$ and $\psi_f = \psi_g = 1$.

since the latter two do not leverage the predictive information in idiosyncratic elements. However, the superior performance compared to PCR-LASSO is interesting. As observed in Online Appendix Tables A11-A14, this can be attributed to the high false positive rates in the case of PCR-LASSO. We provide a possible explanation below.

It is noteworthy that, with regards to the estimation of ‘relevant’ idiosyncratic elements, 3PRF-LASSO and PCR-LASSO yield very similar results.¹⁴ However, with regard to the ‘not-relevant’ idiosyncratic elements, i.e., $\{\varepsilon_i | \gamma_i \neq 0\}$, the estimated value from our procedure differs markedly from their estimates in the PCR setup. For the case of PCR, it is known that $\hat{\varepsilon}_{it}^{PCR} - \varepsilon_{it} = o_p(1)$, as shown in Proposition 5 of Bai & Ng [2023]. For our procedure, Lemma 9 in the Online Appendix shows that $\hat{\varepsilon}_{it}^{3PRF} - (\varepsilon_{it} + \mathbf{g}'_t \boldsymbol{\phi}_{ig} - \bar{\mathbf{g}}' \boldsymbol{\phi}_{ig}) = O_p(\Xi_{NT}^{-1})$.¹⁵ According to Assumption 1, for ‘relevant’ idiosyncratic elements, $\boldsymbol{\phi}_{ig} = 0$, leading to an outcome similar to PCR, i.e., $\forall i \in S, \hat{\varepsilon}_{it}^{3PRF} - \varepsilon_{it} = O_p(\Xi_{NT}^{-1}) = o_p(1)$. However, for ‘not-relevant’ idiosyncratic elements, as observed from lemma 9 of Online Appendix, the convergent limit of $\hat{\varepsilon}_{it}^{3PRF}$ differs from $\hat{\varepsilon}_{it}^{PCR}$. The estimator of idiosyncratic elements in our setup is not consistent for ‘not-relevant’ idiosyncratic elements. This inconsistency, however, is not detrimental since these predictors have a coefficient of 0.

Our setup naturally leads us to a situation where the estimated values of ‘relevant’ idiosyncratic elements are either orthogonal or weakly correlated, while the estimated values of ‘not-relevant’ idiosyncratic elements are highly correlated due to the presence of irrelevant factors. As noted in Zou & Hastie [2005] and Wang *et al.* [2011], “*When the model includes several highly correlated variables, all of which are related to some extent to the response variable, LASSO tends to pick only one or a few of them and shrink the rest to 0.*”. This suggests that high correlation dampens the cardinality of the set of non-zero coefficients in LASSO. When this high correlation is between the relevant predictors and the irrelevant predictors (as in Fan *et al.* [2020]) or amongst relevant predictors, this is an undesirable feature, but when the correlation is high amongst the irrelevant predictors only, this could be a desirable feature since it suppresses the false positive rate. This rationalizes the result

Additional simulations in the Online Appendix confirm that these results hold across various factor strengths and numbers of irrelevant factors.

¹⁴We do not report these results in our simulations, but this can be easily checked by regressing estimated ‘relevant’ idiosyncratic elements from PCA and stage-2 3PRF on each other. We found that it was very close to 1.

¹⁵The super-scripts 3PRF and PCR are used here to emphasize that the idiosyncratic elements are generated from two different methods. However, throughout the paper, $\hat{\varepsilon}_{it}$ denotes the estimated idiosyncratic element using stage-2 3PRF-LASSO, unless stated otherwise.

in Tables A11-A14 of the Online Appendix where we observe high false positive rates in the second stage of PCR-LASSO procedure compared to 3PRF-LASSO. discussed in the following paragraph.

We corroborate our findings as discussed in the previous paragraph with an additional experiment.¹⁶ We generate a vector $\mathbf{x}_{105 \times 1}$ from a multivariate normal distribution. The first five elements of \mathbf{x} are uncorrelated with others and amongst themselves. The rest of the variables in \mathbf{x} have a covariance matrix with diagonal elements being 1 and off-diagonal elements being ρ . We generate 100 independent samples of the target \mathbf{y} as follows: $y_{t+1} = \sum_{i=1}^5 \beta x_{it} + u_{t+1}$. u_{t+1} is generated from a standard normal distribution for each t and is serially uncorrelated. We vary the signal (β) and the correlation between the irrelevant predictors (ρ). This experiment is repeated 100 times and we note the average false and true positive rates. Results are reported in Table 15 of the Online Appendix. The false positive rate considerably decreases when we increase ρ (for all signal levels β). The true positive rate is relatively high, across ρ , even for lower signal levels, but at the lowest signal level, i.e., $\beta = 0.1$, we observe a jump in true positive rates as we increase ρ .

Therefore, the correlation between irrelevant predictors appears to be beneficial as it suppresses spurious selections. This also explains the improved performance of our estimator 3PRF-LASSO compared to PCR-LASSO when we increase the number of irrelevant factors from 4 to 5.

The tables in this paper presents a subset of the simulation results discussed in Section 5. Additional simulation results, evaluating the effect of sample sizes across varying numbers of factors and factor strength combinations, are provided in the Online Appendix. True and false positive rates, as well as the simulation results for the stylized example in the final paragraph of this Section, are also reported in the Online Appendix.

6 Empirical Application

In our empirical analysis, we assess the forecastability of four key U.S. macroeconomic aggregates: Gross Domestic Product, Exports, the GDP Deflator, and Housing Starts. The first two variables are production-related, while the GDP Deflator reflects price movements. Housing Starts is included due to its role in previous empirical work by Fan *et al.* [2023a],

¹⁶The results are given in Online Appendix Table A15.

which found that combining factor and sparse regression methods outperformed both Principal Component Regression and LASSO in predicting Housing Starts in the Northeast. For our study, we analyze overall Housing Starts across the United States.

These variables, along with their predictors, are obtained from the FRED-QD dataset, published by [Clark & McCracken \[2023\]](#). The target variables—Gross Domestic Product, Exports, the GDP Deflator, and Housing Starts—correspond respectively to the dataset codes ‘GDPC1’, ‘EXPGSC1’, ‘GDPCTPI’, and ‘HOUST’. Each series is transformed following the method by [Hamilton & Xi \[2024\]](#) to address non-stationarity, a common challenge in macroeconomic data analysis as noted by [Beveridge & Nelson \[1981\]](#) and [Nelson & Plosser \[1982\]](#). All variables are standardized to account for the sensitivity of the 3PRF method to differences in scale, similar to the scaling sensitivity in Principal Component Analysis (PCA). Standardization ensures that no variable disproportionately influences the results due to its scale.

Prior to forecasting, both target and predictor data undergo partial transformations with respect to a constant and four lags of the target variable, following the approach by [Kelly & Pruitt \[2015\]](#), [Bai & Ng \[2008\]](#), [Stock & Watson \[2012\]](#). This generates the following variables:

$$\begin{aligned}\ddot{y}_{t+h} &= y_{t+h} - \hat{\mathbb{E}}(y_{t+h} \mid y_t, y_{t-1}, y_{t-2}, y_{t-3}) \\ \ddot{\mathbf{x}}_t &= \mathbf{x}_t - \hat{\mathbb{E}}(\mathbf{x}_t \mid y_t, y_{t-1}, y_{t-2}, y_{t-3})\end{aligned}$$

As a consequence of these transformations, some observations are lost, leading to a dataset spanning from 1963:Q3 to 2019:Q3. The COVID-19 period is deliberately excluded due to its outlier nature, rendering it unforecastable. Our forecasting horizon encompasses one quarter ($h=1$) to one year ($h=4$).

The determination of the number of (PC) factors is based on the eigenvalue ratio method introduced by [Ahn & Horenstein \[2013\]](#), yielding one factor for all training samples. This aligns with the findings of [Kelly & Pruitt \[2015\]](#), who also observed one factor using the information criteria by [Bai & Ng \[2002\]](#) in their dataset. Since the number of target-relevant factors is equal to or fewer than those that drive the set of predictors, we use one factor for our 3PRF forecasts. Also, as argued in *Remark 1*, choosing a single factor may be a prudent choice under many circumstances.

We employ a recursive window approach to construct out-of-sample forecasts of the aforementioned series similar to [Kelly & Pruitt \[2015\]](#) and present OOS R-squared values for different methods. The initial training sample (which expands recursively) spans the following time periods, 1963:Q3 - 1997:Q3, encompassing 60 percent of the total observations.

For the second-stage LASSO regression in both 3PRF-LASSO and PCR-LASSO, we employ a 10-fold cross-validation technique to estimate parameters within each training sample, following the approach in [Fan *et al.* \[2020\]](#). The results are presented in [Table 7](#). We forecast four variables across four horizons, yielding a total of 16 comparisons (i.e., across four variables and four horizons).

In each of these comparisons, 3PRF-LASSO or PCR-LASSO consistently outperforms the standard 3PRF and PCR methods, demonstrating the utility of combining sparse and dense regression techniques in forecasting these macroeconomic variables. Specifically, out of the 16 combinations, 3PRF-LASSO emerges as the best-performing method in nine cases and the second-best in five, with only two instances where it does not feature among the top two methods. Furthermore, in these two instances, it closely trails the second-best method, underscoring its reliability.

Overall, 3PRF-LASSO proves to be a robust forecasting technique for high-dimensional datasets, especially where both factor structure and sparsity are likely to be present.

7 Conclusion

Our paper extends the framework developed in [Kelly & Pruitt \[2015\]](#) by addressing two critical aspects of factor-based forecasting models: accommodating weak factors and leveraging potentially informative idiosyncratic components by incorporating them as additional regressors (in addition to factors) through a second stage penalized regression (LASSO). From a theoretical standpoint, our contribution lies in demonstrating how the weakness of factors impacts the convergence rate of the estimator, leading to slower rates as relevant factors become less pervasive. Importantly, we establish that when relevant factors are stronger than irrelevant ones, the Three-Pass Regression Filter (3PRF) achieves a faster convergence rate to the infeasible best forecast compared to Principal Component Regression (PCR). This advantage arises because 3PRF can isolate and utilize relevant factors more effectively in the presence of irrelevant ones.

Allowing idiosyncratic components to have predictive power for the target and, by extension, the proxies (which have a similar DGP as the target) necessitates expanding the underlying model assumptions. We show that, under mild assumptions, this extension does not impose any penalty on convergence rates. If factors are strong, as in [Kelly & Pruitt \[2015\]](#), the convergence rate of 3PRF within a framework where idiosyncratic dependence is allowed would be identical to the case where idiosyncratic dependence is absent, i.e., the setting in the paper by [Kelly & Pruitt \[2015\]](#). This result underscores the robustness of 3PRF in adapting to more general DGPs without sacrificing theoretical efficiency.

On the methodological front, we enhance 3PRF by incorporating a second-stage LASSO regression to capture predictive content from idiosyncratic components. This integration allows the model to effectively utilize residual variation that is not explained by common factors. Our empirical analysis, using macroeconomic data, highlights the practical significance of this extension, demonstrating substantial improvements in the predictability of key macroeconomic variables when idiosyncratic information is included.

Notes: $K_f, K_g, \rho_f, \rho_g, a, d, \psi_f, \psi_g$, Oracle denotes the infeasible R^2 as described in Section 5. PCR denotes the regression of y on first ' K ' Principal components, where $K = K_f + K_g$. 3PRF denotes the auto-proxy 3PRF with K_f auto-proxies. LASSO denotes the R^2 from the LASSO regression of \mathbf{y} on \mathbf{X} . 3PRF+L is 3PRF-LASSO procedure where first Stage 3PRF uses K_f proxies. PCR+L is analogously PCR $K = K_f + K_g$ PCs in the first Stage regression, augmented with second Stage LASSO step. The highest R^2 value across competing methods in in bold.

Online Appendix of

“Forecasting using Supervised Factors and Idiosyncratic Elements”

Daanish Padha[†]

Tae-Hwy Lee[‡]

This appendix is organized as follows. Section [A1](#) provides supplementary lemmas that are used throughout the proofs. Section [A2](#) includes proofs of Theorems 1(a), 2, 3(a), and 4(a), covering stage 1 results of 3PRF-Lasso for the cases when $\gamma = 0$, and $\zeta = 0$. The lemmas used in these proofs are also contained in Section [A2](#). Section [A3](#) addresses Theorems 1(b), 3(b), and 4(b), which focus on stage 1 results of 3PRF-Lasso for $\gamma \neq 0$ and $\zeta \neq 0$. Section [A4](#) presents the stage 2 results of 3PRF-Lasso, i.e, the proof of Theorem 5 and the supporting lemmas for this proof. The final Section [A5](#) contains additional simulation results discussed in Section 5 of the main paper.

A1 Supplementary Lemmas

Lemma 1. *Under Assumptions 2-3, for all s, t, i, m, m_1, m_2 and $v = f, g$ the following results hold.*

1. $\mathbb{E} \left| (NT)^{-1/2} \sum_{i,s} F_s(m) [\varepsilon_{is}\varepsilon_{it} - \sigma_{ii,st}] \right|^2 \leq M.$
2. $\mathbb{E} \left| (NT)^{-1/2} \sum_{i,s} \omega_s(m) [\varepsilon_{is}\varepsilon_{it} - \sigma_{ii,st}] \right|^2 \leq M.$
3. $N^{-1/2}T^{-1/2} \sum_{i,t} \varepsilon_{it} = O_p(1), \quad N^{-1/2} \sum_i \varepsilon_{it} = O_p(1) \quad \text{and} \quad T^{-1/2} \sum_t \varepsilon_{it} = O_p(1).$
4. $T^{-1/2} \sum_t \eta_{t+h} = O_p(1).$
5. $T^{-1/2} \sum_t F_t(m) \eta_{t+h} = O_p(1) \quad \text{and} \quad T^{-1/2} \sum_t \omega_t(m) \eta_{t+h} = O_p(1).$
6. $N^{-1/2}T^{-1/2} \sum_{i,t} \varepsilon_{it} \eta_{t+h} = O_p(1).$
7. $N^{-\psi_v/2}T^{-1} \sum_{i,t} \phi_{iv}(m_1) \varepsilon_{it} F_t(m_2) = O_p(1).$
8. $N^{-\psi_v/2}T^{-1} \sum_{i,t} \phi_{iv}(m_1) \varepsilon_{it} \omega_t(m_2) = O_p(1).$
9. $N^{-\psi_v/2}T^{-1/2} \sum_{i,t} \phi_{iv}(m) \varepsilon_{it} \eta_{t+h} = O_p(1).$
10. (a) $N^{-1}T^{-1/2} \sum_{i,s} \varepsilon_{is} \varepsilon_{it} = O_p(\delta_{NT}^{-1}) \quad \text{and} \quad (b) \quad N^{-1/2}T^{-1} \sum_{i,t} \varepsilon_{it} \varepsilon_{jt} = O_p(\delta_{NT}^{-1}).$
11. $N^{-1}T^{-3/2} \sum_{i,s,t} \varepsilon_{is} \varepsilon_{it} \eta_{t+h} = O_p(\delta_{NT}^{-1}).$
12. $N^{-1}T^{-1/2} \sum_{i,s} F_s(m) \varepsilon_{is} \varepsilon_{it} = O_p(\delta_{NT}^{-1}).$
13. $N^{-1}T^{-1/2} \sum_{i,s} \omega_s(m) \varepsilon_{is} \varepsilon_{it} = O_p(\delta_{NT}^{-1}).$
14. $N^{-1}T^{-1} \sum_{i,s,t} F_s(m) \varepsilon_{is} \varepsilon_{it} \eta_{t+h} = O_p(1).$
15. $N^{-1}T^{-1} \sum_{i,s,t} \omega_s(m) \varepsilon_{is} \varepsilon_{it} \eta_{t+h} = O_p(1).$
16. $N^{-\psi_v/2}T^{-1} \sum_{i,t} \phi_{iv}(m) \varepsilon_{it} \varepsilon_{jt} = O_p(\Gamma_{N_v T}^{-1}).$

The stochastic order is understood to hold as $N, T \rightarrow \infty$, $\delta_{NT} \equiv \min(\sqrt{N}, \sqrt{T})$, $\Gamma_{N_v T} \equiv \min(\sqrt{N^{\psi_v}}, \sqrt{T})$.

Proof: Item 1-4, 6 10(a) and 11-15 have been proved in Kelly & Pruitt [2015], Auxiliary Lemma 1. We prove the rest below.

Item 5: Given Assumption 2.5, we have that

$$\begin{aligned}\mathbb{E} \left| T^{-1/2} \sum_t F_t(m) \eta_{t+h} \right|^2 &= T^{-1} \sum_t \mathbb{E} [\eta_{t+h}^2] \mathbb{E} [F_t(m)^2] \\ &\leq T^{-1} \sum_t \delta_\eta M \\ &= O(1)\end{aligned}$$

by Assumption 2.1 and 2.5. Therefore,

$$T^{-1/2} \sum_t F_t(m) \eta_{t+h} = O_p(1),$$

and similarly,

$$\sum_t \omega_t(m) \eta_{t+h} = O_p(1)$$

using Assumption 2.4, 2.5.

Item 7: For $v \in \{f, g\}$, Using the Cauchy Schwartz inequality,

$$\begin{aligned}N^{-\psi_v/2} T^{-1} \sum_{i,t} \phi_{iv}(m_1) \varepsilon_{it} F_t(m_2) &\leq \left(T^{-1} \sum_t F_t(m_2)^2 \right)^{1/2} \left(T^{-1} \sum_t \left[N^{-\psi_v/2} \sum_i \phi_{iv}(m) \varepsilon_{it} \right]^2 \right)^{1/2} \\ &= O_p(1) O_p(1)\end{aligned}$$

by Assumptions 3.7 and 2.1.

Item 8: $v \in \{f, g\}$, Using the Cauchy Schwartz inequality,

$$\begin{aligned}N^{-\psi_v/2} T^{-1} \sum_{i,t} \phi_{iv}(m_1) \varepsilon_{it} \omega_t(m_2) &\leq \left(T^{-1} \sum_t \omega_t(m_2)^2 \right)^{1/2} \left(T^{-1} \sum_t \left[N^{-\psi_v/2} \sum_i \phi_{iv}(m) \varepsilon_{it} \right]^2 \right)^{1/2} \\ &= O_p(1) O_p(1)\end{aligned}$$

by Assumptions 3.7 and 2.4.

Item 9 : Since $\mathbb{E}[\eta_{t+1} \eta_{s+1}] = 0$ for $t \neq s$ and η_{t+h} is independent of $\phi_i(m)$ and $\varepsilon_{i,t}$, $\forall i, t$ for

any $h > 0$ by Assumption 2.5, we have,

$$\begin{aligned}
\mathbb{E} \left| N^{-\psi_v/2} T^{-1/2} \sum_{i,t} \phi_i(m) \varepsilon_{it} \eta_{t+h} \right|^2 &= N^{-\psi_v} T^{-1} \sum_{i,j,t} \mathbb{E} [\phi_i(m) \phi_j(m) \varepsilon_{it} \varepsilon_{jt} \eta_{t+h}^2] \\
&= T^{-1} \sum_t \mathbb{E} [\eta_{t+h}^2] \mathbb{E} \left[\left(N^{-\psi_v/2} \sum_i \phi_i(m) \varepsilon_{it} \right)^2 \right] \\
&= O_p(1) O_p(1).
\end{aligned}$$

Last line follows from Assumptions 3.7 and 2.5.

Item 10(b):

$$\begin{aligned}
N^{-1/2} T^{-1} \sum_{i,t} \varepsilon_{it} \varepsilon_{jt} &= N^{-1/2} T^{-1} \sum_{i,t} [\varepsilon_{it} \varepsilon_{jt} - \sigma_{ij,tt}] + N^{-1/2} T^{-1} \sum_{i,t} \sigma_{ij,tt} \\
&= O_p(T^{-1/2}) + O_p(N^{-1/2})
\end{aligned}$$

by Assumption 3.2(b) and 3.1(d).

Item 16 : We have,

$$\begin{aligned}
N^{-\psi_v/2} T^{-1} \sum_{i,t} \phi_{iv}(m) \varepsilon_{it} \varepsilon_{jt} &= T^{-1/2} \left(N^{-\psi_v/2} T^{-1/2} \sum_{i,t} \phi_{iv}(m) [\varepsilon_{it} \varepsilon_{jt} - \sigma_{ij,tt}] \right) \\
&\quad + N^{-\psi_v/2} \left(T^{-1} \sum_{i,t} \phi_{iv}(m) \sigma_{ij,tt} \right) \\
&= 16.I + 16.II.
\end{aligned}$$

16.I is $O_p(T^{-1/2})$ by Assumption 3.3.

16.II is $O_p(N^{-\psi_v/2})$ since $\mathbb{E} \left| T^{-1} \sum_{i,t} \phi_{iv}(m) \sigma_{ij,tt} \right| \leq \max_i \mathbb{E} |\phi_{iv}(m)| T^{-1} \sum_{i,t} |\sigma_{ij,tt}| = O_p(1)$ by Assumption 2.2 and 3.1(d). Hence, $N^{-\psi_v/2} T^{-1} \sum_{i,t} \phi_{iv}(m) \varepsilon_{it} \varepsilon_{jt} = O_p(\Gamma_{N_v T}^{-1})$.

Lemma 2. Under Assumption(s) 2-3, we have the following

1. $T^{-1/2} \mathbf{F}' \mathbf{J}_T \boldsymbol{\omega} = O_p(1)$.
2. $T^{-1/2} \mathbf{F}' \mathbf{J}_T \boldsymbol{\eta} = O_p(1)$.
3. $T^{-1/2} \boldsymbol{\varepsilon}' \mathbf{J}_T \boldsymbol{\eta} = O_p(1)$.

$$4. N^{-\psi_f} \boldsymbol{\varepsilon}'_t \mathbf{J}_N \boldsymbol{\Phi} = \mathcal{O}_p \left(N^{-\frac{\psi_f}{2}} \vee N^{-\psi_f + \frac{\psi_g}{2}} \right).$$

$$5. N^{-\psi_f} T^{-1} \boldsymbol{\Phi}' \mathbf{J}_N \boldsymbol{\varepsilon}' \mathbf{J}_T \mathbf{F} = \mathcal{O}_p \left(\Gamma_{N_f T}^{-1} \vee \frac{N^{\psi_g - \psi_f}}{\Gamma_{N_g T}} \right).$$

$$6. N^{-\psi_f} T^{-1} \boldsymbol{\Phi}' \mathbf{J}_N \boldsymbol{\varepsilon}' \mathbf{J}_T \boldsymbol{\omega} = \mathcal{O}_p \left(\Gamma_{N_f T}^{-1} \vee \frac{N^{\psi_g - \psi_f}}{\Gamma_{N_g T}} \right).$$

$$7. N^{-\psi_f} T^{-1/2} \boldsymbol{\Phi}' \mathbf{J}_N \boldsymbol{\varepsilon}' \mathbf{J}_T \boldsymbol{\eta} = \mathcal{O}_p \left(N^{-\frac{\psi_f}{2}} \vee N^{-\psi_f + \frac{\psi_g}{2}} \right).$$

$$8. N^{-1} T^{-3/2} \mathbf{F}' \mathbf{J}_T \boldsymbol{\varepsilon} \mathbf{J}_N \boldsymbol{\varepsilon}' \mathbf{J}_T \mathbf{F} = \mathcal{O}_p (\delta_{NT}^{-1}).$$

$$9. N^{-1} T^{-3/2} \boldsymbol{\omega}' \mathbf{J}_T \boldsymbol{\varepsilon} \mathbf{J}_N \boldsymbol{\varepsilon}' \mathbf{J}_T \mathbf{F} = \mathcal{O}_p (\delta_{NT}^{-1}).$$

$$10. N^{-1} T^{-3/2} \boldsymbol{\omega}' \mathbf{J}_T \boldsymbol{\varepsilon} \mathbf{J}_N \boldsymbol{\varepsilon}' \mathbf{J}_T \boldsymbol{\omega} = \mathcal{O}_p (\delta_{NT}^{-1}).$$

$$11. N^{-1} T^{-1/2} \mathbf{F}' \mathbf{J}_T \boldsymbol{\varepsilon} \mathbf{J}_N \boldsymbol{\varepsilon}_t = \mathcal{O}_p (\delta_{NT}^{-1}).$$

$$12. N^{-1} T^{-1/2} \boldsymbol{\omega}' \mathbf{J}_T \boldsymbol{\varepsilon} \mathbf{J}_N \boldsymbol{\varepsilon}_t = \mathcal{O}_p (\delta_{NT}^{-1}).$$

$$13. N^{-1} T^{-3/2} \boldsymbol{\eta}' \mathbf{J}_T \boldsymbol{\varepsilon} \mathbf{J}_N \boldsymbol{\varepsilon}' \mathbf{J}_T \mathbf{F} = \mathcal{O}_p (\delta_{NT}^{-1}).$$

$$14. N^{-1} T^{-3/2} \boldsymbol{\eta}' \mathbf{J}_T \boldsymbol{\varepsilon} \mathbf{J}_N \boldsymbol{\varepsilon}' \mathbf{J}_T \mathbf{F} = \mathcal{O}_p (\delta_{NT}^{-1}).$$

Proof: Item 1-3 and 8-14 have been proved in Kelly & Pruitt [2015], Auxiliary Lemma 2.

We prove the rest below.

Expanding Item 4 we have,

$$N^{-\psi_f} \boldsymbol{\varepsilon}'_t \mathbf{J}_N \boldsymbol{\Phi} = \begin{bmatrix} N^{-\psi_f} \boldsymbol{\varepsilon}'_t \mathbf{J}_N \boldsymbol{\Phi}_f & N^{\psi_g - \psi_f} (N^{-\psi_g} \boldsymbol{\varepsilon}'_t \mathbf{J}_N \boldsymbol{\Phi}_g) \end{bmatrix}.$$

m^{th} element of $N^{-\psi_f} \boldsymbol{\varepsilon}'_t \mathbf{J}_N \boldsymbol{\Phi}_f$ is given by,

$$N^{-\psi_f/2} \left(N^{-\psi_f/2} \sum_i \varepsilon_{it} \phi_{if}(m) - \left(N^{-1+\psi_f/2} \sum_i \varepsilon_{it} \right) \left(N^{-\psi_f} \sum_i \phi_{if}(m) \right) \right) = N^{-\psi_f/2} (1.\text{I} + 1.\text{II})$$

1.I : This term is $\mathcal{O}_p(1)$ by Assumption 3.7.

1.II : Since $N^{-1/2} \sum_i \varepsilon_{it} = \mathcal{O}_p(1)$ by Lemma 1.3, we have $N^{-1+\frac{\psi_f}{2}} \sum_i \varepsilon_{it} = \mathcal{O}_p(1)$ as

$0 < \psi_f \leq 1$. By Assumption 2.2, $N^{-\psi_f} \sum_i \phi_{if}(m) = \mathcal{O}_p(1)$. Hence, (I + II) is $\mathcal{O}_p(1)$.

Therefore,

$$\begin{aligned} N^{-\psi_f} \boldsymbol{\varepsilon}'_t \mathbf{J}_N \boldsymbol{\Phi}_f &= N^{-\psi_f/2} \mathbf{O}_p(1) \\ &= \mathbf{O}_p\left(N^{-\psi_f/2}\right). \end{aligned}$$

Similarly,

$$N^{-\psi_g} \boldsymbol{\varepsilon}'_t \mathbf{J}_N \boldsymbol{\Phi}_g = \mathbf{O}_p\left(N^{-\psi_g/2}\right),$$

which implies

$$N^{-\psi_f} \boldsymbol{\varepsilon}'_t \mathbf{J}_N \boldsymbol{\Phi}_g = \mathbf{O}_p\left(N^{\psi_g - \psi_f} \times N^{-\psi_g/2}\right).$$

Hence, the whole matrix has the following order.

$$N^{-\psi_f} \boldsymbol{\varepsilon}'_t \mathbf{J}_N \boldsymbol{\Phi} = \mathbf{O}_p\left(N^{-\psi_f/2} \vee N^{-\psi_f + \psi_g/2}\right).$$

Item 5 can be expanded as

$$N^{-\psi_f} T^{-1} \boldsymbol{\Phi}'_f \mathbf{J}_N \boldsymbol{\varepsilon}' \mathbf{J}_T \mathbf{F} = \begin{pmatrix} N^{-\psi_f} T^{-1} \boldsymbol{\Phi}'_f \mathbf{J}_N \boldsymbol{\varepsilon}' \mathbf{J}_T \mathbf{F} \\ N^{-\psi_f + \psi_g} (N^{-\psi_g} T^{-1} \boldsymbol{\Phi}'_g \mathbf{J}_N \boldsymbol{\varepsilon}' \mathbf{J}_T \mathbf{F}) \end{pmatrix}.$$

We show that $N^{-\psi_f} T^{-1} \boldsymbol{\Phi}'_f \mathbf{J}_N \boldsymbol{\varepsilon}' \mathbf{J}_T \mathbf{F}$ is $\mathbf{O}_p\left(\Gamma_{N_f T}^{-1}\right)$. By symmetry, $N^{-\psi_g} T^{-1} \boldsymbol{\Phi}'_g \mathbf{J}_N \boldsymbol{\varepsilon}' \mathbf{J}_T \mathbf{F}$ will be $\mathbf{O}_p\left(\Gamma_{N_g T}^{-1}\right)$. Hence $N^{-\psi_f + \psi_g} (N^{-\psi_g} T^{-1} \boldsymbol{\Phi}'_g \mathbf{J}_N \boldsymbol{\varepsilon}' \mathbf{J}_T \mathbf{F})$ is $\mathbf{O}_p\left(\frac{N^{\psi_g - \psi_f}}{\Gamma_{N_g T}}\right)$ and therefore the whole matrix is $\mathbf{O}_p\left(\Gamma_{N_f T}^{-1} \vee \frac{N^{\psi_g - \psi_f}}{\Gamma_{N_g T}}\right)$. Therefore, it's sufficient to show $N^{-\psi_f} T^{-1} \boldsymbol{\Phi}'_f \mathbf{J}_N \boldsymbol{\varepsilon}' \mathbf{J}_T \mathbf{F}$ is $\mathbf{O}_p\left(\Gamma_{N_f T}^{-1}\right)$ and the stochastic order for the matrix follows. We show this below.

$N^{-\psi_f} T^{-1} \boldsymbol{\Phi}'_f \mathbf{J}_N \boldsymbol{\varepsilon}' \mathbf{J}_T \mathbf{F}$ is a $K_f \times K$ matrix with generic (m_1, m_2) element given by,

$$\begin{aligned} & N^{-\psi_f} T^{-1} \sum_{i,t} \phi_{if}(m_1) F_t(m_2) \varepsilon_{it} - N^{-\psi_f - 1} T^{-1} \sum_{i,j,t} \phi_{if}(m_1) F_t(m_2) \varepsilon_{jt} \\ & - N^{-\psi_f} T^{-2} \sum_{j,s,t} F_s(m_2) \phi_{jf}(m_1) \varepsilon_{jt} + N^{-\psi_f - 1} T^{-2} \sum_{i,j,s,t} F_s(m_2) \phi_{if}(m_1) \varepsilon_{jt} \\ & = 5.I - 5.II - 5.III + 5.IV. \end{aligned}$$

5.I is $\mathbf{O}_p\left(N^{-\psi_f/2}\right)$ by Lemma 1.7.

5.II is $\mathbf{O}_p\left(T^{-1/2}\right)$ since $N^{-\psi_f} \sum_i \phi_{if}(m_1) = \mathbf{O}_p(1)$ by Assumption 2.2 and

$N^{-1} \sum_j (T^{-1/2} \sum_t F_t(m_2) \varepsilon_{jt}) = O_p(1)$ by Assumption 3.6.

5.III is $O_p(N^{-\psi_f/2})$ since $T^{-1} \sum_s F_s(m_2) = O_p(1)$ by Assumption 2.1 and

$T^{-1} \sum_t (N^{-\psi_f/2} \sum_j \phi_{jf}(m_1) \varepsilon_{jt}) = O_p(1)$ by Assumption 3.7.

5.IV is $O_p(T^{-1/2} N^{-1/2})$ by Assumptions 2.1, 2.2 and Lemma 1.3.

Summing these terms, $N^{-\psi_f} T^{-1} \Phi_f' J_N \varepsilon' J_T F$ is $O_p(\Gamma_{N_f T}^{-1})$.

Item 6 can be expanded as

$$N^{-\psi_f} T^{-1} \Phi_f' J_N \varepsilon' J_T \omega = \begin{pmatrix} N^{-\psi_f} T^{-1} \Phi_f' J_N \varepsilon' J_T \omega \\ N^{-\psi_f + \psi_g} (N^{-\psi_g} T^{-1} \Phi_g' J_N \varepsilon' J_T \omega) \end{pmatrix}.$$

As in the case of Item 5, it suffices to show that $N^{-\psi_f} T^{-1} \Phi_f' J_N \varepsilon' J_T \omega$ is $O_p(\Gamma_{N_f T}^{-1})$.

$N^{-\psi_f} T^{-1} \Phi_f' J_N \varepsilon' J_T \omega$ is a $K_f \times L$ matrix with generic (m_1, m_2) element given by,

$$\begin{aligned} & N^{-\psi_f} T^{-1} \sum_{i,t} \phi_{if}(m_1) \omega_t(m_2) \varepsilon_{it} - N^{-\psi_f-1} T^{-1} \sum_{i,j,t} \phi_{if}(m_1) \omega_t(m_2) \varepsilon_{jt} \\ & - N^{-\psi_f} T^{-2} \sum_{j,s,t} \omega_s(m_2) \phi_{jf}(m_1) \varepsilon_{jt} + N^{-\psi_f-1} T^{-2} \sum_{i,j,s,t} \omega_s(m_2) \phi_{if}(m_1) \varepsilon_{jt} \\ & = 6.I - 6.II - 6.III + 6.IV. \end{aligned}$$

6.I is $O_p(N^{-\psi_f/2})$ by Lemma 1.8.

6.II is $O_p(T^{-1/2})$ since $N^{-\psi_f} \sum_i \phi_{if}(m_1) = O_p(1)$ by Assumption 2.2 and

$N^{-1} \sum_j (T^{-1/2} \sum_t \omega_t(m_2) \varepsilon_{jt}) = O_p(1)$ by Assumption 3.5.

6.III is $O_p(N^{-\psi_f/2} T^{-1/2})$ since $T^{-1/2} \sum_s \omega_s(m_2) = O_p(1)$ by Assumption 2.4

and $T^{-1} \sum_t (N^{-\psi_f/2} \sum_j \phi_{jf}(m_1) \varepsilon_{jt}) = O_p(1)$ by Assumption 3.7.

6.IV is $O_p(T^{-1} N^{-1/2})$ by Assumption 2.2, 2.4 and Lemma 1.3.

Summing these terms, we have that $N^{-\psi_f} T^{-1} \Phi_f' J_N \varepsilon' J_T \omega$ is $O_p(\Gamma_{N_f T}^{-1})$.

Item 7: Similar to arguments presented in the case of Item 5 and 6, to show that $N^{-\psi_f} T^{-1/2} \Phi_f' J_N \varepsilon' J_T \eta$ is $O_p\left(N^{\frac{-\psi_f}{2}} \vee N^{-\psi_f + \frac{\psi_g}{2}}\right)$, it suffices to show that $N^{-\psi_f} T^{-1/2} \cdot \Phi_f' J_N \varepsilon' J_T \eta$ is $O_p\left(N^{\frac{-\psi_f}{2}}\right)$.

We show this below.

m^{th} element of $N^{-\psi_f} T^{-1/2} \Phi_f' J_N \epsilon' J_T \eta$ is given by,

$$\begin{aligned} & N^{-\psi_f} T^{-1/2} \sum_{i,t} \phi_{if}(m) \varepsilon_{it} \eta_{t+h} - N^{-\psi_f} T^{-3/2} \sum_{i,s,t} \phi_{if}(m) \varepsilon_{it} \eta_{s+h} \\ & - N^{-\psi_f-1} T^{-1/2} \sum_{i,j,t} \phi_{if}(m) \varepsilon_{jt} \eta_{t+h} + N^{-\psi_f-1} T^{-3/2} \sum_{i,j,s,t} \phi_{if}(m) \varepsilon_{jt} \eta_{s+h} \\ & = 7.I - 7.II - 7.III + 7.IV. \end{aligned}$$

7.I is $O_p(N^{-\psi_f/2})$ by Lemma 1.9.

7.II can be written as

$$N^{-\psi_f/2} \left(T^{-1} \sum_t \left[N^{-\psi_f/2} \sum_i \phi_{if}(m) \varepsilon_{it} \right] \right) \left(T^{-1/2} \sum_s \eta_{s+h} \right).$$

This is $O_p(N^{-\psi_f/2})$ by Assumption 3.7 and Lemma 1.4.

7.III can be written as

$$\begin{aligned} & \left(N^{-\psi_f} \sum_i \phi_{if}(m) \right) \left(N^{-1/2} T^{-1/2} \sum_{j,t} \varepsilon_{jt} \eta_{t+h} \right) (N^{-1/2}) \\ & = O_p(1) O_p(1) (N^{-1/2}). \end{aligned}$$

This follows from Assumption 2.2 and Lemma 1.6.

7.IV can be written as

$$\begin{aligned} & \left(N^{-1/2} T^{-1/2} \sum_{j,t} \varepsilon_{jt} \right) \left(T^{-1/2} \sum_s \eta_{s+h} \right) \left(N^{-\psi_f} \sum_i \phi_{if}(m) \right) (N^{-1/2} \times T^{-1/2}) \\ & = O_p(1) O_p(1) O_p(1) (N^{-1/2} \times T^{-1/2}) \\ & = O_p(N^{-1/2} \times T^{-1/2}). \end{aligned}$$

This follows from Assumption 2.2 Lemma 1.3 and 1.4.

Summing these terms, $N^{-\psi_f} T^{-1/2} \Phi_f' J_N \epsilon' J_T \eta$ is $O_p(N^{-\psi_f/2})$.

Lemma 3. Under Assumptions 2-3, we have,

$$1. N^{-2\psi_f} T^{-1} \Phi' J_N \epsilon' J_T \epsilon J_N \Phi = O_p \left(N^{-\psi_f/2} \Gamma_{N_f T}^{-1} \vee \frac{N^{2(\psi_g - \psi_f)}}{N^{\psi_g/2} \Gamma_{N_g T}} \right).$$

$$\begin{aligned}
2. \quad & N^{-2\psi_f} T^{-2} \mathbf{\Phi}' \mathbf{J}_N \mathbf{\varepsilon}' \mathbf{J}_T \mathbf{\varepsilon} \mathbf{J}_N \mathbf{\varepsilon}' \mathbf{J}_T \mathbf{F} = O_p \left(T^{-1/2} N^{-\frac{3\psi_f}{2}+1} \delta_{NT}^{-1} \vee \frac{N^{2(\psi_g-\psi_f)}}{T^{1/2} N^{\frac{3\psi_g}{2}-1} \delta_{NT}} \right). \\
3. \quad & N^{-2\psi_f} T^{-2} \mathbf{\Phi}' \mathbf{J}_N \mathbf{\varepsilon}' \mathbf{J}_T \mathbf{\varepsilon} \mathbf{J}_N \mathbf{\varepsilon}' \mathbf{J}_T \boldsymbol{\omega} = O_p \left(T^{-1/2} N^{-\frac{3\psi_f}{2}+1} \delta_{NT}^{-1} \vee \frac{N^{2(\psi_g-\psi_f)}}{T^{1/2} N^{\frac{3\psi_g}{2}-1} \delta_{NT}} \right). \\
4. \quad & N^{-2\psi_f} T^{-3} \mathbf{F}' \mathbf{J}_T \mathbf{\varepsilon} \mathbf{J}_N \mathbf{\varepsilon}' \mathbf{J}_T \mathbf{\varepsilon} \mathbf{J}_N \mathbf{\varepsilon}' \mathbf{J}_T \mathbf{F} = O_p \left(\left(\frac{N^{1-\psi_f}}{\sqrt{T} \delta_{NT}} \right)^2 \right). \\
5. \quad & N^{-2\psi_f} T^{-3} \mathbf{F}' \mathbf{J}_T \mathbf{\varepsilon} \mathbf{J}_N \mathbf{\varepsilon}' \mathbf{J}_T \mathbf{\varepsilon} \mathbf{J}_N \mathbf{\varepsilon}' \mathbf{J}_T \boldsymbol{\omega} = O_p \left(\left(\frac{N^{1-\psi_f}}{\sqrt{T} \delta_{NT}} \right)^2 \right). \\
6. \quad & N^{-2\psi_f} T^{-3} \boldsymbol{\omega}' \mathbf{J}_T \mathbf{\varepsilon} \mathbf{J}_N \mathbf{\varepsilon}' \mathbf{J}_T \mathbf{\varepsilon} \mathbf{J}_N \mathbf{\varepsilon}' \mathbf{J}_T \boldsymbol{\omega} = O_p \left(\left(\frac{N^{1-\psi_f}}{\sqrt{T} \delta_{NT}} \right)^2 \right).
\end{aligned}$$

Proof: We prove 1-3 below. 4-6 have been proved in Kelly & Pruitt [2015], Online Appendix, Lemma Web. They show that $N^{-2} T^{-3} \mathbf{F}' \mathbf{J}_T \mathbf{\varepsilon} \mathbf{J}_N \mathbf{\varepsilon}' \mathbf{J}_T \mathbf{\varepsilon} \mathbf{J}_N \mathbf{\varepsilon}' \mathbf{J}_T \mathbf{F}$, $N^{-2} T^{-3} \mathbf{F}' \mathbf{J}_T \mathbf{\varepsilon} \mathbf{J}_N \mathbf{\varepsilon}' \mathbf{J}_T \mathbf{\varepsilon} \mathbf{J}_N \mathbf{\varepsilon}' \mathbf{J}_T \boldsymbol{\omega}$ and $N^{-2} T^{-3} \boldsymbol{\omega}' \mathbf{J}_T \mathbf{\varepsilon} \mathbf{J}_N \mathbf{\varepsilon}' \mathbf{J}_T \mathbf{\varepsilon} \mathbf{J}_N \mathbf{\varepsilon}' \mathbf{J}_T \boldsymbol{\omega}$ are all $O_p(T^{-1} \delta_{NT}^{-2})$. Therefore changing N^{-2} in the normalization term by $N^{-2\psi_f}$ gives the stochastic orders as listed in Lemma 3 above.

Item 1 is $K \times K$ matrix given as,

$$N^{-2\psi_f} T^{-1} \mathbf{\Phi}' \mathbf{J}_N \mathbf{\varepsilon}' \mathbf{J}_T \mathbf{\varepsilon} \mathbf{J}_N \mathbf{\Phi} = \begin{bmatrix} N^{-2\psi_f} T^{-1} \mathbf{\Phi}'_f \mathbf{J}_N \mathbf{\varepsilon}' \mathbf{J}_T \mathbf{\varepsilon} \mathbf{J}_N \mathbf{\Phi}_f & N^{-2\psi_f} T^{-1} \mathbf{\Phi}'_f \mathbf{J}_N \mathbf{\varepsilon}' \mathbf{J}_T \mathbf{\varepsilon} \mathbf{J}_N \mathbf{\Phi}_g \\ N^{-2\psi_f} T^{-1} \mathbf{\Phi}'_g \mathbf{J}_N \mathbf{\varepsilon}' \mathbf{J}_T \mathbf{\varepsilon} \mathbf{J}_N \mathbf{\Phi}_f & N^{-2\psi_f} T^{-1} \mathbf{\Phi}'_g \mathbf{J}_N \mathbf{\varepsilon}' \mathbf{J}_T \mathbf{\varepsilon} \mathbf{J}_N \mathbf{\Phi}_g \end{bmatrix}.$$

First, We show that $N^{-2\psi_f} T^{-1} \mathbf{\Phi}'_f \mathbf{J}_N \mathbf{\varepsilon}' \mathbf{J}_T \mathbf{\varepsilon} \mathbf{J}_N \mathbf{\Phi}_f$ is $O_p(N^{-\psi_f/2} \Gamma_{N_f T}^{-1})$.

$N^{-2\psi_f} T^{-1} \mathbf{\Phi}'_f \mathbf{J}_N \mathbf{\varepsilon}' \mathbf{J}_T \mathbf{\varepsilon} \mathbf{J}_N \mathbf{\Phi}_f$ has generic (m_1, m_2) element given as

$$\begin{aligned}
& N^{-2\psi_f} T^{-1} \sum_{i,j,t} \phi_{fi}(m_1) \varepsilon_{it} \varepsilon_{jt} \phi_{fj}(m_2) - N^{-2\psi_f-1} T^{-1} \sum_{i,j,k,t} \phi_{fi}(m_1) \varepsilon_{it} \varepsilon_{jt} \phi_{fk}(m_2) \\
& - N^{-2\psi_f-1} T^{-1} \sum_{i,j,k,t} \phi_{fi}(m_1) \varepsilon_{jt} \varepsilon_{kt} \phi_{fk}(m_2) + N^{-2\psi_f-2} T^{-1} \sum_{i,j,k,l,t} \phi_{fi}(m_1) \varepsilon_{jt} \varepsilon_{kt} \phi_{fl}(m_2) \\
& - N^{-2\psi_f} T^{-2} \sum_{i,j,s,t} \phi_{fi}(m_1) \varepsilon_{is} \varepsilon_{jt} \phi_{fj}(m_2) + N^{-2\psi_f-1} T^{-2} \sum_{i,j,k,s,t} \phi_{fi}(m_1) \varepsilon_{is} \varepsilon_{jt} \phi_{fk}(m_2) \\
& + N^{-2\psi_f-1} T^{-2} \sum_{i,j,k,s,t} \phi_{fi}(m_1) \varepsilon_{js} \varepsilon_{kt} \phi_{fk}(m_2) - N^{-2\psi_f-2} T^{-2} \sum_{i,j,k,l,s,t} \phi_{fi}(m_1) \varepsilon_{js} \varepsilon_{kt} \phi_{fl}(m_2) \\
& = \text{I.I} - \dots - \text{I.VIII}.
\end{aligned}$$

1.I can be written as

$$N^{-\psi_f} \left(T^{-1} \sum_t \left(N^{-\psi_f/2} \sum_i \phi_{fi}(m_1) \varepsilon_{it} \right) \left(N^{-\psi_f/2} \sum_j \phi_{fj}(m_2) \varepsilon_{jt} \right) \right) \\ = O_p \left(N^{-\psi_f} \right)$$

by Assumption 3.7.

1.II can be written as

$$N^{-\psi_f/2} \left(N^{-1} \sum_j N^{-\psi_f/2} T^{-1} \sum_{i,t} \phi_{fi}(m_1) \varepsilon_{it} \varepsilon_{jt} \right) \left(N^{-\psi_f} \sum_k \phi_{fk}(m_2) \right) \\ = O_p \left(N^{-\psi_f/2} \Gamma_{N_f T}^{-1} \right)$$

by lemma 1.16 and Assumption 2.2.

1.III is $O_p \left(N^{-\psi_f/2} \Gamma_{N_f T}^{-1} \right)$, proof is identical to 1.II.

1.IV can be written as

$$N^{-1/2} \left(N^{-\psi_f} \sum_i \phi_{fi}(m_1) \right) \left(N^{-\psi_f} \sum_l \phi_{fl}(m_2) \right) \left(N^{-1} \sum_k N^{-1/2} T^{-1} \sum_{j,t} \varepsilon_{jt} \varepsilon_{kt} \right) \\ = N^{-1/2} O_p(1) O_p(1) O_p(\delta_{NT}^{-1}) \\ = O_p \left(\delta_{NT}^{-1} N^{-1/2} \right)$$

by Assumption 2.2 and Lemma 1.10.

1.V is $O_p \left(N^{-\psi_f} \right)$. Identical to 1.I.

1.VI can be written as

$$N^{\frac{-\psi_f-1}{2}} T^{\frac{-1}{2}} \left(T^{-1} \sum_s N^{-\psi_f/2} \sum_i \phi_{fi}(m_1) \varepsilon_{is} \right) \\ \times \left(T^{-1/2} N^{-1/2} \sum_{j,t} \varepsilon_{jt} \right) \left(N^{-\psi_f} \sum_k \phi_{fk}(m_2) \right) \\ = N^{\frac{-\psi_f-1}{2}} T^{\frac{-1}{2}} O_p(1) O_p(1) O_p(1) \\ = O_p \left(N^{\frac{-\psi_f-1}{2}} T^{\frac{-1}{2}} \right)$$

by Assumption 2.2, 3.7 and Lemma 1.10.

1.VII is $O_p\left(N^{-\frac{\psi_f-1}{2}}T^{-\frac{1}{2}}\right)$. Identical to 1.VI

1.VIII can be written as

$$\begin{aligned} & N^{-1}T^{-1} \left(N^{-\psi_f} \sum_i \phi_{fi}(m_1) \right) \left(N^{-1/2}T^{-1/2} \sum_{js} \varepsilon_{js} \right) \\ & \times \left(N^{-1/2}T^{-1/2} \sum_{kt} \varepsilon_{kt} \right) \left(N^{-\psi_f} \sum_l \phi_{fl}(m_2) \right) \\ & = N^{-1}T^{-1} O_p(1) O_p(1) O_p(1) \\ & = O_p(N^{-1}T^{-1}) \end{aligned}$$

by Assumptions 2.2 and Lemma 1.3.

Summing all these terms gives us $N^{-2\psi_f}T^{-1}\Phi_f'J_N\varepsilon'J_T\varepsilon J_N\Phi_f$ is $O_p\left(N^{-\psi_f/2}\Gamma_{N_fT}^{-1}\right)$.

By a symmetrical argument $N^{-2\psi_g}T^{-1}\Phi_g'J_N\varepsilon'J_T\varepsilon J_N\Phi_g$ is $O_p\left(N^{-\psi_g/2}\Gamma_{N_gT}^{-1}\right)$.

Hence, $N^{-2\psi_f}T^{-1}\Phi_g'J_N\varepsilon'J_T\varepsilon J_N\Phi_g$ is $O_p\left(\frac{N^{2(\psi_g-\psi_f)}}{N^{\psi_g/2}\Gamma_{N_gT}}\right)$.

It is also easy to see from the proof presented above, that, depending on whether ψ_f is greater, equal to or less than ψ_g , $N^{-2\psi_f}T^{-1}\Phi_g'J_N\varepsilon'J_T\varepsilon J_N\Phi_f$ is either $O_p\left(N^{-\psi_f/2}\Gamma_{N_fT}^{-1}\right)$ (when $\psi_f > \psi_g$) or $O_p\left(\frac{N^{2(\psi_g-\psi_f)}}{N^{\psi_g/2}\Gamma_{N_gT}}\right)$ (when $\psi_f < \psi_g$). When $\psi_f = \psi_g$, the two rates are equal.

Therefore, the matrix $N^{-2\psi_f}T^{-1}\Phi_f'J_N\varepsilon'J_T\varepsilon J_N\Phi$ is $O_p\left(N^{-\psi_f/2}\Gamma_{N_fT}^{-1} \vee \frac{N^{2(\psi_g-\psi_f)}}{N^{\psi_g/2}\Gamma_{N_gT}}\right)$.

Item 2 is given by

$$N^{-2\psi_f}T^{-2}\Phi_f'J_N\varepsilon'J_T\varepsilon J_N\varepsilon'J_T\mathbf{F} = \begin{bmatrix} N^{-2\psi_f}T^{-2}\Phi_f'J_N\varepsilon'J_T\varepsilon J_N\varepsilon'J_T\mathbf{F} \\ N^{-2\psi_f}T^{-2}\Phi_g'J_N\varepsilon'J_T\varepsilon J_N\varepsilon'J_T\mathbf{F} \end{bmatrix}.$$

We first show (below) that $K_f \times K$ matrix $N^{-2\psi_f}T^{-2}\Phi_f'J_N\varepsilon'J_T\varepsilon J_N\varepsilon'J_T\mathbf{F}$ is $O_p\left(N^{-\psi_f/2}\Gamma_{N_fT}^{-1}\right)$.

The matrix $N^{-2\psi_f}T^{-2}\Phi_f'J_N\epsilon'J_T\epsilon J_N\epsilon'J_TF$ has generic (m_1, m_2) element,

$$\begin{aligned}
& N^{-2\psi_f}T^{-2}\sum_{i,j,s}\phi_{jf}(m_1)\epsilon_{jt}\epsilon_{it}\epsilon_{is}F_s(m_2) - N^{-2\psi_f}T^{-3}\sum_{i,j,s,t,u}\phi_{jf}(m_1)\epsilon_{ju}\epsilon_{iu}\epsilon_{it}F_s(m_2) \\
& - N^{-2\psi_f-1}T^{-2}\sum_{i,j,k,s,t}\phi_{kf}(m_1)\epsilon_{kt}\epsilon_{jt}\epsilon_{is}F_s(m_2) + N^{-2\psi_f-1}T^{-3}\sum_{i,j,k,s,t,u}\phi_{kf}(m_1)\epsilon_{ku}\epsilon_{ju}\epsilon_{it}F_s(m_2) \\
& - N^{-2\psi_f}T^{-3}\sum_{i,j,s,t,u}\phi_{jf}(m_1)\epsilon_{ju}\epsilon_{it}\epsilon_{is}F_s(m_2) + N^{-2\psi_f}T^{-4}\sum_{i,j,s,t,u,v}\phi_{jf}(m_1)\epsilon_{jv}\epsilon_{iu}\epsilon_{it}F_s(m_2) \\
& + N^{-2\psi_f-1}T^{-3}\sum_{i,j,k,s,t,u}\phi_{kf}(m_1)\epsilon_{ku}\epsilon_{jt}\epsilon_{is}F_s(m_2) - N^{-2\psi_f-1}T^{-4}\sum_{i,j,k,s,t,u,v}\phi_{kf}(m_1)\epsilon_{kv}\epsilon_{ju}\epsilon_{it}F_s(m_2) \\
& - N^{-2\psi_f-1}T^{-2}\sum_{i,j,k,s,t}\phi_{kf}(m_1)\epsilon_{jt}\epsilon_{it}\epsilon_{is}F_s(m_2) + N^{-2\psi_f-1}T^{-3}\sum_{i,j,k,s,t,u}\phi_{kf}(m_1)\epsilon_{ju}\epsilon_{iu}\epsilon_{it}F_s(m_2) \\
& + N^{-2\psi_f-2}T^{-2}\sum_{i,j,k,l,s,t}\phi_{lf}(m_1)\epsilon_{kt}\epsilon_{jt}\epsilon_{is}F_s(m_2) - N^{-2\psi_f-2}T^{-3}\sum_{i,j,k,l,s,t,u}\phi_{lf}(m_1)\epsilon_{ku}\epsilon_{ju}\epsilon_{it}F_s(m_2) \\
& + N^{-2\psi_f-1}T^{-3}\sum_{i,j,k,s,t,u}\phi_{kf}(m_1)\epsilon_{ju}\epsilon_{it}\epsilon_{is}F_s(m_2) - N^{-2\psi_f-1}T^{-4}\sum_{i,j,k,s,t,u,v}\phi_{kf}(m_1)\epsilon_{jv}\epsilon_{iu}\epsilon_{it}F_s(m_2) \\
& - N^{-2\psi_f-2}T^{-3}\sum_{i,j,k,l,s,t,u}\phi_{lf}(m_1)\epsilon_{ku}\epsilon_{jt}\epsilon_{is}F_s(m_2) + N^{-2\psi_f-2}T^{-4}\sum_{i,j,k,l,s,t,u,v}\phi_{lf}(m_1)\epsilon_{kv}\epsilon_{ju}\epsilon_{it}F_s(m_2) \\
& = 2.I - \dots - 2.XVI.
\end{aligned}$$

2.I Using Cauchy Schwartz inequality, this term is bounded by

$$\begin{aligned}
& N^{-\frac{3\psi_f}{2}+1}T^{-1/2}\left(T^{-1}\sum_t[N^{-\psi_f/2}\sum_j\phi_{jf}(m_1)\epsilon_{jt}]^2\right)^{\frac{1}{2}}\left(T^{-1}\sum_t[N^{-1}T^{-1/2}\sum_{i,s}\epsilon_{is}F_s(m_2)\epsilon_{it}]^2\right)^{\frac{1}{2}} \\
& = N^{-\frac{3\psi_f}{2}+1}T^{-1/2}O_p(\delta_{NT}^{-1})O_p(1) \\
& = O_p(T^{-1/2}N^{-\frac{3\psi_f}{2}+1}\delta_{NT}^{-1})
\end{aligned}$$

by Lemma 1.12 and Assumption 3.7.

2.II: Using Cauchy Schwartz inequality, this term is bounded by,

$$\begin{aligned}
& N^{-\frac{3\psi_f}{2}+1}T^{-1/2}\left(T^{-1}\sum_u[N^{-\psi_f/2}\sum_j\phi_{jf}(m_1)\epsilon_{ju}]^2\right)^{\frac{1}{2}}\left(T^{-1}\sum_u[N^{-1}T^{-1/2}\sum_{i,t}\epsilon_{it}\epsilon_{iu}]^2\right)^{\frac{1}{2}} \\
& \times \left(T^{-1}\sum_sF_s(m_2)\right).
\end{aligned}$$

This is $O_p(\delta_{NT}^{-1}T^{-1/2}N^{-\frac{3\psi_f}{2}+1})$ by Lemma 1.10(b), Assumption 2.1 and 3.7.

2.III can be written as

$$N^{-\frac{3\psi_f}{2}+1}T^{-1/2} \left(N^{-\psi_f} \sum_k \phi_{k_f}(m_1) \left[N^{-1/2}T^{-1} \sum_{j,t} \varepsilon_{kt} \varepsilon_{jt} \right] \right) \\ \times \left(N^{-1} \sum_i T^{-1/2} \sum_s \varepsilon_{is} F_s(m_2) \right).$$

This is equal to $N^{\frac{1}{2}-\psi_f}T^{-1/2}O_p(\delta_{NT}^{-1})O_p(1)$ which is $O_p(\delta_{NT}^{-1}T^{-1/2}N^{\frac{1}{2}-\psi_f})$ by Lemma 1.10(b) and Assumption 2.2 and 3.6.

2.IV can be written as

$$N^{-\frac{3\psi_f+1}{2}}T^{-1/2} \left(N^{-1} \sum_j N^{-\psi_f/2}T^{-1} \sum_{k,u} \phi_{k_f}(m_1) \varepsilon_{ku} \varepsilon_{ju} \right) \\ \times \left(N^{-1/2}T^{-1/2} \sum_{i,t} \varepsilon_{it} \right) \left(T^{-1} \sum_s F_s(m_2) \right).$$

This is $O_p(\Gamma_{N_f T}^{-1}N^{-\frac{3\psi_f+1}{2}}T^{-1/2})$ by Lemma 1.3 and 1.16, Assumption 2.1.

2.V can be written as

$$N^{-\frac{3\psi_f}{2}+1}T^{-1/2} \left(T^{-1} \sum_u N^{-\psi_f/2} \sum_{j=1} \phi_{j_f}(m_1) \varepsilon_{ju} \right) \\ \times \left(T^{-1} \sum_t N^{-1}T^{-1/2} \sum_{i,s} F_s(m_2) \varepsilon_{is} \varepsilon_{it} \right).$$

This is $O_p(\delta_{NT}^{-1}T^{-1/2}N^{-\frac{3\psi_f}{2}+1})$ by Assumption 3.7 and Lemma 1.12.

2.VI can be written as

$$N^{-\frac{3\psi_f}{2}+1}T^{-1/2} \left(T^{-1} \sum_v \left(N^{-\psi_f/2} \sum_j \phi_{j_f}(m_1) \varepsilon_{jv} \right) \right) \\ \times \left(T^{-1} \sum_t N^{-1}T^{-1/2} \sum_{i,u} \varepsilon_{iu} \varepsilon_{it} \right) \left(T^{-1} \sum_s F_s(m_2) \right).$$

This is $O_p(\delta_{NT}^{-1}N^{-\frac{3\psi_f}{2}+1}T^{-1/2})$ by Assumption 2.1, 3.7 and Lemma 1.10.

2.VII can be written as

$$N^{-\frac{3\psi_f+1}{2}}T^{-1} \left(T^{-1} \sum_u N^{-\psi_f/2} \sum_k \phi_{k_f}(m_1) \varepsilon_{ku} \right) \\ \times \left(N^{-1/2}T^{-1/2} \sum_{j,t} \varepsilon_{jt} \right) \left(N^{-1} \sum_i T^{-1/2} \sum_s \varepsilon_{is} F_s(m_2) \right).$$

This is $O_p(N^{-\frac{3\psi_f+1}{2}}T^{-1})$ by Assumption 3.6, 3.7 and Lemma 1.3.

2.VIII can be written as

$$N^{-\frac{3\psi_f}{2}}T^{-1} \left(T^{-1} \sum_v N^{-\psi_f/2} \sum_k \phi_{k_f}(m_1) \varepsilon_{kv} \right) \left(N^{-1/2}T^{-1/2} \sum_{j,u} \varepsilon_{ju} \right) \\ \times \left(N^{-1/2}T^{-1/2} \sum_{i,t} \varepsilon_{it} \right) \left(T^{-1} \sum_s F_s(m_2) \right).$$

This is $O_p(N^{-\frac{3\psi_f}{2}}T^{-1})$ by Assumption 3.6 and Lemma 1.3.

2.IX: Using Cauchy Schwartz, this term is bounded by

$$N^{-\psi_f+\frac{1}{2}}T^{-1/2} \left(N^{-\psi_f} \sum_k \phi_{k_f}(m_1) \right) \left(T^{-1} \sum_t \left[N^{-\frac{1}{2}} \sum_j \varepsilon_{jt} \right]^2 \right)^{1/2} \\ \times \left(T^{-1} \sum_t \left[N^{-1}T^{-\frac{1}{2}} \sum_{i,s} F_s(m_2) \varepsilon_{is} \varepsilon_{it} \right] \right)^{1/2},$$

which is $O_p(N^{-\psi_f+\frac{1}{2}}T^{-1/2}\delta_{NT}^{-1})$ by Lemma 1.3, Lemma 1.14 and Assumption 2.2.

2.X: Using Cauchy Schwartz, this term is bounded by

$$N^{-\psi_f+\frac{1}{2}}T^{-1/2} \left(N^{-\psi_f} \sum_k \phi_{k_f}(m_1) \right) \left(T^{-1} \sum_u \left[N^{-\frac{1}{2}} \sum_j \varepsilon_{ju} \right]^2 \right)^{1/2} \\ \times \left(T^{-1} \sum_u \left[N^{-1}T^{-\frac{1}{2}} \sum_{i,t} \varepsilon_{iu} \varepsilon_{it} \right] \right)^{1/2},$$

which is $O_p(N^{-\psi_f+\frac{1}{2}}T^{-1/2}\delta_{NT}^{-1})$ by Assumptions 2.1, 2.2, Lemma 1.3 and Lemma 1.10.

2.XI can be written as

$$N^{-\psi_f + \frac{1}{2}} T^{-1/2} \left(N^{-\psi_f} \sum_l \phi_{l_f}(m_1) \right) \left(N^{-1} \sum_j \left[N^{-\frac{1}{2}} T^{-1} \sum_{k,t} \varepsilon_{jt} \varepsilon_{kt} \right] \right) \\ \times \left(N^{-1} \sum_i T^{-1/2} \sum_s \varepsilon_{is} F_s(m_2) \right).$$

This is $O_p(N^{-\psi_f + \frac{1}{2}} T^{-1/2} \delta_{NT}^{-1})$ by Assumptions 2.2, 3.6 and Lemma 1.10.

2.XII can be written as

$$N^{-\psi_f} T^{-1/2} \left(N^{-\psi_f} \sum_l \phi_{l_f}(m_1) \right) \left(N^{-1} \sum_k \left[N^{-\frac{1}{2}} T^{-1} \sum_{j,u} \varepsilon_{ju} \varepsilon_{ku} \right] \right) \\ \times \left(N^{-\frac{1}{2}} T^{-\frac{1}{2}} \sum_{t,t} \varepsilon_{it} \right) \left(T^{-1} \sum_s F_s(m_2) \right).$$

This is $O_p(N^{-\psi_f} T^{-1/2} \delta_{NT}^{-1})$ by Assumption 2.2, 2.3 and Lemma 1.10.

2.XIII Using Cauchy Schwartz, this term is bounded by

$$N^{-\psi_f + 1/2} T^{-1/2} \left(N^{-\psi_f} \sum_k \phi_{k_f}(m_1) \right) \left(N^{-1/2} T^{-1/2} \sum_{j,u} \varepsilon_{ju} \right) \\ \times \left(N^{-1} \sum_i [T^{-1/2} \sum_t \varepsilon_{it}^2] \right)^{1/2} \left(N^{-1} \sum_i [T^{-1/2} \sum_s \varepsilon_{is} F_s(m_2)]^2 \right)^{1/2},$$

which is $O_p(N^{-\psi_f + 1/2} T^{-1/2} \delta_{NT}^{-1})$ by Assumption 2.2, 3.6 and Lemma 1.3.

2.XIV can be written as

$$N^{-\psi_f + 1/2} T^{-1/2} \left(N^{-\psi_f} \sum_k \phi_{k_f}(m_1) \right) \left(N^{-1/2} T^{-1/2} \sum_{i,t} \varepsilon_{it} \right) \\ \times \left(N^{-1} \sum_u \left[N^{-1/2} T^{-1} \sum_{i,t} \varepsilon_{it} \varepsilon_{iu} \right] \right) \left(T^{-1} \sum_s F_s(m_2) \right).$$

This is $O_p(N^{-\psi_f} T^{-1/2} \delta_{NT}^{-1})$ by Assumption 2.2, 2.3, Lemma 1.3 and 1.10.

2.XV can be written as

$$N^{-\psi_f} T^{-3/2} \left(N^{-\psi_f} \sum_l \phi_{l_f}(m_1) \right) \left(N^{-1/2} T^{-1/2} \sum_{k,u} \varepsilon_{ku} \right) \\ \times \left(N^{-1/2} T^{-1/2} \sum_{j,t} \varepsilon_{jt} \right) \left(N^{-1} \sum_i T^{-1/2} \sum_s \varepsilon_{is} F_s(m_2) \right).$$

This is $O_p(N^{-\psi_f} T^{-3/2})$ by Assumption 2.2, 3.6 and Lemma 1.3.

2.XVI can be written as

$$N^{-\psi_f - \frac{1}{2}} T^{-3/2} \left(N^{-\psi_f} \sum_l \phi_{l_f}(m_1) \right) \left(N^{-1/2} T^{-1/2} \sum_{k,v} \varepsilon_{kv} \right) \\ \times \left(N^{-1/2} T^{-1/2} \sum_{j,u} \varepsilon_{ju} \right) \left(N^{-1/2} T^{-1/2} \sum_{i,t} \varepsilon_{it} \right) \left(T^{-1} \sum_s F_s(m_2) \right).$$

This is $O_p(N^{-\psi_f - \frac{1}{2}} T^{-3/2})$ by Assumption 2.1, 2.2, Lemma 1.3.

Since $0 < \psi_f \leq 1$, the initial terms dominate the order. Thus, summing all these terms yields:

$$N^{-2\psi_f} T^{-2} \Phi'_f \mathbf{J}_N \varepsilon' \mathbf{J}_T \varepsilon \mathbf{J}_N \varepsilon' \mathbf{J}_T \mathbf{F} = O_p \left(T^{-\frac{1}{2}} N^{-\frac{3\psi_f}{2} + 1} \delta_{NT}^{-1} \right).$$

By a symmetrical argument, we have:

$$N^{-2\psi_g} T^{-2} \Phi'_g \mathbf{J}_N \varepsilon' \mathbf{J}_T \varepsilon \mathbf{J}_N \varepsilon' \mathbf{J}_T \mathbf{F} = O_p \left(T^{-\frac{1}{2}} N^{-\frac{3\psi_g}{2} + 1} \delta_{NT}^{-1} \right).$$

Hence, we can conclude that:

$$N^{-2\psi_f} T^{-2} \Phi'_g \mathbf{J}_N \varepsilon' \mathbf{J}_T \varepsilon \mathbf{J}_N \varepsilon' \mathbf{J}_T \mathbf{F} = O_p \left(\frac{N^{2(\psi_g - \psi_f)}}{T^{1/2} N^{\frac{3\psi_g}{2} - 1} \delta_{NT}} \right).$$

Therefore, we have:

$$N^{-2\psi_f} T^{-2} \Phi'_f \mathbf{J}_N \varepsilon' \mathbf{J}_T \varepsilon \mathbf{J}_N \varepsilon' \mathbf{J}_T \mathbf{F} = O_p \left(T^{-\frac{1}{2}} N^{-\frac{3\psi_f}{2} + 1} \delta_{NT}^{-1} \vee \frac{N^{2(\psi_g - \psi_f)}}{T^{1/2} N^{\frac{3\psi_g}{2} - 1} \delta_{NT}} \right).$$

Item 3 is $K \times M$ matrix and the proof follows the same logic as Item 2, replacing $F_s(m_2)$ by $\omega_s(m_2)$.

A2 Proofs of Theorem 1(a), 2, 3(a) and 4(a)

We introduce 2 Lemmas which are utilized in proofs of stage 1 results of 3PRF-Lasso for the cases when $\gamma = 0$, and $\zeta = 0$. The proofs are presented subsequent to these Lemmas.

Lemma 4. Recall, $\Xi_{NT}^{-1} \equiv T^{-1/2} \vee N^{-\psi_f/2} \vee \left(\frac{N^{\psi_g - \psi_f}}{\Gamma_{N_g T}} \right)$ which is equivalent to $T^{-1/2} \vee N^{-\psi_f/2} \vee N^{-\psi_f + \psi_g/2} \vee \left(\frac{N^{\psi_g - \psi_f}}{\sqrt{T}} \right)$.

Under Assumptions **1-6**, if $\frac{N^{1-\psi_f}}{\sqrt{T}} = O(1)$, if $\gamma = 0$, and $\zeta = 0$, we have,

1. $\hat{\mathbf{F}}_A = T^{-1} \mathbf{Z}' \mathbf{J}_T \mathbf{Z} = \mathbf{\Lambda}_f \mathbf{\Delta}_f \mathbf{\Lambda}'_f + \mathbf{\Delta}_\omega + O_p(T^{-1/2})$.
2. $\hat{\mathbf{F}}_B = N^{-\psi_f} T^{-2} \mathbf{Z}' \mathbf{J}_T \mathbf{X} \mathbf{J}_N \mathbf{X}' \mathbf{J}_T \mathbf{Z} = \mathbf{\Lambda}_f \mathbf{\Delta}_f \mathcal{P}_f \mathbf{\Delta}_f \mathbf{\Lambda}'_f + O_p(\Xi_{NT}^{-1})$.
3. $\hat{\mathbf{F}}_{C,t} = N^{-\psi_f} T^{-1} \mathbf{Z}' \mathbf{J}_T \mathbf{X} \mathbf{J}_N \mathbf{x}_t = N^{-\psi_f} T^{-1} \mathbf{Z}' \mathbf{J}_T \mathbf{X} \mathbf{J}_N \phi_0 + \mathbf{\Lambda}_f \mathbf{\Delta}_f \mathcal{P}_f \mathbf{f}_t + O_p(\Xi_{NT}^{-1})$.

Furthermore, the probability limits of $\hat{\mathbf{\Phi}}'$ and $\hat{\mathbf{F}}_t$ are

$$\hat{\mathbf{\Phi}}' \xrightarrow[T \rightarrow \infty]{p} (\mathbf{\Lambda}_f \mathbf{\Delta}_f \mathbf{\Lambda}'_f + \mathbf{\Delta}_\omega)^{-1} \mathbf{\Lambda}_f \mathbf{\Delta}_f \mathbf{\Phi}'_f,$$

and

$$\hat{\mathbf{F}}_t \xrightarrow[T, N \rightarrow \infty]{p} (\mathbf{\Lambda}_f \mathbf{\Delta}_f \mathbf{\Lambda}'_f + \mathbf{\Delta}_\omega) (\mathbf{\Lambda}_f \mathbf{\Delta}_f \mathcal{P}_f \mathbf{\Delta}_f \mathbf{\Lambda}'_f)^{-1} \left(N^{-\psi_f} T^{-1} \mathbf{Z}' \mathbf{J}_T \mathbf{X} \mathbf{J}_N \phi_0 + \mathbf{\Lambda}_f \mathbf{\Delta}_f \mathcal{P}_f \mathbf{f}_t \right).$$

Proof:

First we note that

$$\begin{aligned} N^{-\psi_f} \mathbf{\Phi}' \mathbf{J}_N \mathbf{\Phi} &= \begin{bmatrix} N^{-\psi_f} \mathbf{\Phi}'_f \mathbf{J}_N \mathbf{\Phi}_f & N^{-\psi_f} \mathbf{\Phi}'_f \mathbf{J}_N \mathbf{\Phi}_g \\ N^{-\psi_f} \mathbf{\Phi}'_g \mathbf{J}_N \mathbf{\Phi}_f & N^{\psi_g - \psi_f} (N^{-\psi_g} \mathbf{\Phi}'_g \mathbf{J}_N \mathbf{\Phi}_g) \end{bmatrix} \\ &= O_p(1 \vee N^{\psi_g - \psi_f}). \end{aligned} \tag{A2.1}$$

The final equality follows from Assumption **2.2** and **4.1**.

Item 1 :

$$\begin{aligned}
\hat{\mathbf{F}}_A &= T^{-1} \mathbf{Z}' \mathbf{J}_T \mathbf{Z} \\
&= \mathbf{\Lambda} (T^{-1} \mathbf{F}' \mathbf{J}_T \mathbf{F}) \mathbf{\Lambda}' + \mathbf{\Lambda} (T^{-1} \mathbf{F}' \mathbf{J}_T \boldsymbol{\omega}) + (T^{-1} \boldsymbol{\omega}' \mathbf{J}_T \mathbf{F}) \mathbf{\Lambda}' + T^{-1} \boldsymbol{\omega}' \mathbf{J}_T \boldsymbol{\omega} \\
&= \mathbf{\Lambda} \boldsymbol{\Delta}_F \mathbf{\Lambda}' + \boldsymbol{\Delta}_\omega + \mathcal{O}_p(T^{-1/2}) \\
&= \mathbf{\Lambda}_f \boldsymbol{\Delta}_f \mathbf{\Lambda}'_f + \boldsymbol{\Delta}_\omega + \mathcal{O}_p(T^{-1/2}).
\end{aligned}$$

The first equality follows from assumptions 2.1, 2.4 and Lemma 2.1 and final equality follows from the fact that $\boldsymbol{\Delta}_F$ is block diagonal (Assumption 4) and $\mathbf{\Lambda} = \begin{bmatrix} \mathbf{\Lambda}_f & \mathbf{0} \end{bmatrix}$ by Assumption 5.

Item 2:

$$\begin{aligned}
\hat{\mathbf{F}}_B &= N^{-\psi_f} T^{-2} \mathbf{Z}' \mathbf{J}_T \mathbf{X} \mathbf{J}_N \mathbf{X}' \mathbf{J}_T \mathbf{Z} \\
&= \mathbf{\Lambda} (T^{-1} \mathbf{F}' \mathbf{J}_T \mathbf{F}) \left(N^{-\psi_f} \boldsymbol{\Phi}' \mathbf{J}_N \boldsymbol{\Phi} \right) (T^{-1} \mathbf{F}' \mathbf{J}_T \mathbf{F}) \mathbf{\Lambda}' + \mathbf{\Lambda} (T^{-1} \mathbf{F}' \mathbf{J}_T \mathbf{F}) \left(N^{-\psi_f} \boldsymbol{\Phi}' \mathbf{J}_N \boldsymbol{\Phi} \right) (T^{-1} \mathbf{F}' \mathbf{J}_T \boldsymbol{\omega}) \\
&\quad + \mathbf{\Lambda} (T^{-1} \mathbf{F}' \mathbf{J}_T \mathbf{F}) \left(N^{-\psi_f} T^{-1} \boldsymbol{\Phi}' \mathbf{J}_N \boldsymbol{\varepsilon}' \mathbf{J}_T \mathbf{F} \right) \mathbf{\Lambda}' + \mathbf{\Lambda} (T^{-1} \mathbf{F}' \mathbf{J}_T \mathbf{F}) \left(N^{-\psi_f} T^{-1} \boldsymbol{\Phi}' \mathbf{J}_N \boldsymbol{\varepsilon}' \mathbf{J}_T \boldsymbol{\omega} \right) \\
&\quad + \mathbf{\Lambda} \left(N^{-\psi_f} T^{-1} \mathbf{F}' \mathbf{J}_T \boldsymbol{\varepsilon} \mathbf{J}_N \boldsymbol{\Phi} \right) (T^{-1} \mathbf{F}' \mathbf{J}_T \mathbf{F}) \mathbf{\Lambda}' + \mathbf{\Lambda} \left(N^{-\psi_f} T^{-1} \mathbf{F}' \mathbf{J}_T \boldsymbol{\varepsilon} \mathbf{J}_N \boldsymbol{\Phi} \right) (T^{-1} \mathbf{F}' \mathbf{J}_T \boldsymbol{\omega}) \\
&\quad + \frac{N^{1-\psi_f}}{\sqrt{T}} \mathbf{\Lambda} \left(N^{-1} T^{-3/2} \mathbf{F}' \mathbf{J}_T \boldsymbol{\varepsilon} \mathbf{J}_N \boldsymbol{\varepsilon}' \mathbf{J}_T \mathbf{F} \right) \mathbf{\Lambda}' + \frac{N^{1-\psi_f}}{\sqrt{T}} \mathbf{\Lambda} \left(N^{-1} T^{-3/2} \mathbf{F}' \mathbf{J}_T \boldsymbol{\varepsilon} \mathbf{J}_N \boldsymbol{\varepsilon}' \mathbf{J}_T \boldsymbol{\omega} \right) \\
&\quad + (T^{-1} \boldsymbol{\omega}' \mathbf{J}_T \mathbf{F}) \left(N^{-\psi_f} \boldsymbol{\Phi}' \mathbf{J}_N \boldsymbol{\Phi} \right) (T^{-1} \mathbf{F}' \mathbf{J}_T \mathbf{F}) \mathbf{\Lambda}' + (T^{-1} \boldsymbol{\omega}' \mathbf{J}_T \mathbf{F}) \left(N^{-\psi_f} \boldsymbol{\Phi}' \mathbf{J}_N \boldsymbol{\Phi} \right) (T^{-1} \mathbf{F}' \mathbf{J}_T \boldsymbol{\omega}) \\
&\quad + (T^{-1} \boldsymbol{\omega}' \mathbf{J}_T \mathbf{F}) \left(N^{-\psi_f} T^{-1} \boldsymbol{\Phi}' \mathbf{J}_N \boldsymbol{\varepsilon}' \mathbf{J}_T \mathbf{F} \right) \mathbf{\Lambda}' + (T^{-1} \boldsymbol{\omega}' \mathbf{J}_T \mathbf{F}) \left(N^{-\psi_f} T^{-1} \boldsymbol{\Phi}' \mathbf{J}_N \boldsymbol{\varepsilon}' \mathbf{J}_T \boldsymbol{\omega} \right) \\
&\quad + \left(N^{-\psi_f} T^{-1} \boldsymbol{\omega}' \mathbf{J}_T \boldsymbol{\varepsilon} \mathbf{J}_N \boldsymbol{\Phi} \right) (T^{-1} \mathbf{F}' \mathbf{J}_T \mathbf{F}) \mathbf{\Lambda}' + \left(N^{-\psi_f} T^{-1} \boldsymbol{\omega}' \mathbf{J}_T \boldsymbol{\varepsilon} \mathbf{J}_N \boldsymbol{\Phi} \right) (T^{-1} \mathbf{F}' \mathbf{J}_T \boldsymbol{\omega}) \\
&\quad + \frac{N^{1-\psi_f}}{\sqrt{T}} \left(N^{-\psi_f} T^{-3/2} \boldsymbol{\omega}' \mathbf{J}_T \boldsymbol{\varepsilon} \mathbf{J}_N \boldsymbol{\varepsilon}' \mathbf{J}_T \mathbf{F} \right) \mathbf{\Lambda}' + \frac{N^{1-\psi_f}}{\sqrt{T}} \left(N^{-1} T^{-3/2} \boldsymbol{\omega}' \mathbf{J}_T \boldsymbol{\varepsilon} \mathbf{J}_N \boldsymbol{\varepsilon}' \mathbf{J}_T \boldsymbol{\omega} \right) \\
&= \mathbf{\Lambda} (T^{-1} \mathbf{F}' \mathbf{J}_T \mathbf{F}) \left(N^{-\psi_f} \boldsymbol{\Phi}' \mathbf{J}_N \boldsymbol{\Phi} \right) (T^{-1} \mathbf{F}' \mathbf{J}_T \mathbf{F}) \mathbf{\Lambda}' + \mathcal{O}_p(\Xi_{NT}^{-1}).
\end{aligned}$$

The final equality follows from Assumption 2.1, 4, Lemma 2 and equation A2.1.

Now, using the fact that $\mathbf{\Lambda} = \begin{bmatrix} \mathbf{\Lambda}_f & \mathbf{0} \end{bmatrix}$ (Assumption 5), we have

$$\begin{aligned}
\mathbf{\Lambda} (T^{-1} \mathbf{F}' \mathbf{J}_T \mathbf{F}) (N^{-\psi_f} \mathbf{\Phi}' \mathbf{J}_N \mathbf{\Phi}) (T^{-1} \mathbf{F}' \mathbf{J}_T \mathbf{F}) \mathbf{\Lambda}' &= \mathbf{\Lambda}_f (T^{-1} \mathbf{f}' \mathbf{J}_T \mathbf{f}) (N^{-\psi_f} \mathbf{\Phi}'_f \mathbf{J}_N \mathbf{\Phi}_f) (T^{-1} \mathbf{f}' \mathbf{J}_T \mathbf{f}) \mathbf{\Lambda}'_f \\
&\quad + \mathbf{\Lambda}_f (T^{-1} \mathbf{f}' \mathbf{J}_T \mathbf{f}) (N^{-\psi_f} \mathbf{\Phi}'_f \mathbf{J}_N \mathbf{\Phi}_g) (T^{-1} \mathbf{g}' \mathbf{J}_T \mathbf{f}) \mathbf{\Lambda}'_f \\
&\quad + \mathbf{\Lambda}_f (T^{-1} \mathbf{f}' \mathbf{J}_T \mathbf{g}) (N^{-\psi_f} \mathbf{\Phi}'_g \mathbf{J}_N \mathbf{\Phi}_f) (T^{-1} \mathbf{f}' \mathbf{J}_T \mathbf{f}) \mathbf{\Lambda}'_f \\
&\quad + \frac{N^{\psi_g - \psi_f}}{T} \mathbf{\Lambda}_f (T^{-1/2} \mathbf{f}' \mathbf{J}_T \mathbf{g}) (N^{-\psi_g} \mathbf{\Phi}'_g \mathbf{J}_N \mathbf{\Phi}_g) \\
&\quad \times (T^{-1/2} \mathbf{g}' \mathbf{J}_T \mathbf{f}) \mathbf{\Lambda}'_f \\
&= \mathbf{\Lambda}_f \mathbf{\Delta}_f \mathcal{P}_f \mathbf{\Delta}_f \mathbf{\Lambda}'_f + O_p(\Xi_{NT}^{-1}).
\end{aligned}$$

The final equality follows from Assumption 2.1, 4.

Hence, $\hat{\mathbf{F}}_B$, which is $N^{-\psi_f} T^{-2} \mathbf{Z}' \mathbf{J}_T \mathbf{X} \mathbf{J}_N \mathbf{X}' \mathbf{J}_T \mathbf{Z}$ is equal to $\mathbf{\Lambda}_f \mathbf{\Delta}_f \mathcal{P}_f \mathbf{\Delta}_f \mathbf{\Lambda}'_f + O_p(\Xi_{NT}^{-1})$.

Item 3:

$$\begin{aligned}
\hat{\mathbf{F}}_{C,t} &= N^{-\psi_f} T^{-1} \mathbf{Z}' \mathbf{J}_T \mathbf{X} \mathbf{J}_N \mathbf{x}_t \\
&= \mathbf{\Lambda} (T^{-1} \mathbf{F}' \mathbf{J}_T \mathbf{F}) (N^{-\psi_f} \mathbf{\Phi}' \mathbf{J}_N \phi_0) + \mathbf{\Lambda} (T^{-1} \mathbf{F}' \mathbf{J}_T \mathbf{F}) (N^{-\psi_f} \mathbf{\Phi}' \mathbf{J}_N \mathbf{\Phi}) \mathbf{F}_t \\
&\quad + \mathbf{\Lambda} (T^{-1} \mathbf{F}' \mathbf{J}_T \mathbf{F}) (N^{-\psi_f} \mathbf{\Phi}' \mathbf{J}_N \varepsilon_t) + \mathbf{\Lambda} (N^{-\psi_f} T^{-1} \mathbf{F}' \mathbf{J}_T \varepsilon \mathbf{J}_N \phi_0) \\
&\quad + \mathbf{\Lambda} (N^{-\psi_f} T^{-1} \mathbf{F}' \mathbf{J}_T \varepsilon \mathbf{J}_N \mathbf{\Phi}) \mathbf{F}_t + \frac{N^{1-\psi_f}}{\sqrt{T}} \mathbf{\Lambda} (N^{-1} T^{-1/2} \mathbf{F}' \mathbf{J}_T \varepsilon \mathbf{J}_N \varepsilon_t) \\
&\quad + (T^{-1} \omega' \mathbf{J}_T \mathbf{F}) (N^{-\psi_f} \mathbf{\Phi}' \mathbf{J}_N \phi_0) + (T^{-1} \omega' \mathbf{J}_T \mathbf{F}) (N^{-\psi_f} \mathbf{\Phi}' \mathbf{J}_N \mathbf{\Phi}) \mathbf{F}_t \\
&\quad + (T^{-1} \omega' \mathbf{J}_T \mathbf{F}) (N^{-\psi_f} \mathbf{\Phi}' \mathbf{J}_N \varepsilon_t) + (N^{-1} T^{-1} \omega' \mathbf{J}_T \varepsilon \mathbf{J}_N \phi_0) \\
&\quad + (N^{-\psi_f} T^{-1} \omega' \mathbf{J}_T \varepsilon \mathbf{J}_N \mathbf{\Phi}) \mathbf{F}_t + \frac{N^{1-\psi_f}}{\sqrt{T}} (N^{-1} T^{-1/2} \omega' \mathbf{J}_T \varepsilon \mathbf{J}_N \varepsilon_t) \\
&= N^{-\psi_f} T^{-1} \mathbf{Z}' \mathbf{J}_T \mathbf{X} \mathbf{J}_N \phi_0 + \mathbf{\Lambda} (T^{-1} \mathbf{F}' \mathbf{J}_T \mathbf{F}) (N^{-\psi_f} \mathbf{\Phi}' \mathbf{J}_N \mathbf{\Phi}) \mathbf{F}_t + O_p(\Xi_{NT}^{-1}).
\end{aligned}$$

Assumption 2.1, 4, Lemma 2 and equation A2.1 give the final equality.

Again using Assumption 5; $\Lambda = \begin{bmatrix} \Lambda_f & \mathbf{0} \end{bmatrix}$, we have,

$$\begin{aligned}
\Lambda (T^{-1} \mathbf{F}' J_T \mathbf{F}) (N^{-\psi_f} \Phi' J_N \Phi) \mathbf{F}_t &= \Lambda_f (T^{-1} \mathbf{f}' J_T \mathbf{f}) (N^{-\psi_f} \Phi'_f J_N \Phi_f) \mathbf{f}_t \\
&\quad + \Lambda_f (T^{-1} \mathbf{f}' J_T \mathbf{f}) (N^{-\psi_f} \Phi'_f J_N \Phi_g) \mathbf{g}_t \\
&\quad + \Lambda_f (T^{-1} \mathbf{f}' J_T \mathbf{g}) (N^{-\psi_f} \Phi'_g J_N \Phi_f) \mathbf{f}_t \\
&\quad + \frac{N^{\psi_g - \psi_f}}{\sqrt{T}} \Lambda_f (T^{-1/2} \mathbf{f}' J_T \mathbf{g}) (N^{-\psi_g} \Phi'_g J_N \Phi_g) \mathbf{g}_t \\
&= \Lambda_f \Delta_f \mathcal{P}_f \mathbf{f}_t + O_p(\Xi_{NT}^{-1}).
\end{aligned}$$

The final equality again follows from Assumption 2.1, 4.

Hence, $\hat{\mathbf{F}}_{C,t} = N^{-\psi_f} T^{-1} \mathbf{Z}' J_T \mathbf{X} J_N \mathbf{x}_t = N^{-\psi_f} T^{-1} \mathbf{Z}' J_T \mathbf{X} J_N \phi_0 + \Lambda_f \Delta_f \mathcal{P}_f \mathbf{f}_t + O_p(\Xi_{NT}^{-1})$.

Combining results for Items 1-3, Using Assumption 6, we have,

$$\begin{aligned}
\hat{\mathbf{F}}_t &= T^{-1} \mathbf{Z}' J_T \mathbf{Z} (N^{-\psi_f} T^{-2} \mathbf{Z}' J_T \mathbf{X} J_N \mathbf{X}' J_T \mathbf{Z})^{-1} N^{-\psi_f} T^{-1} \mathbf{Z}' J_T \mathbf{X} J_N \mathbf{x}_t \\
&= \hat{\mathbf{F}}_A \hat{\mathbf{F}}_B^{-1} \hat{\mathbf{F}}_{C,t} \\
&\xrightarrow[T, N \rightarrow \infty]{p} (\Lambda_f \Delta_f \Lambda'_f + \Delta_\omega) (\Lambda_f \Delta_f \mathcal{P}_f \Delta_f \Lambda'_f)^{-1} (N^{-\psi_f} T^{-1} \mathbf{Z}' J_T \mathbf{X} J_N \phi_0 + \Lambda_f \Delta_f \mathcal{P}_f \mathbf{f}_t).
\end{aligned}$$

Similarly expanding $\mathbf{Z}' J_T \mathbf{X}$ gives $\mathbf{Z}' J_T \mathbf{X} = \Lambda_f \Delta_f \Phi'_f + O_p(T^{-1/2})$ and hence,

$$\hat{\Phi}' = (\mathbf{Z}' J_T \mathbf{Z})^{-1} \mathbf{Z}' J_T \mathbf{X} \xrightarrow[T \rightarrow \infty]{p} (\Lambda_f \Delta_f \Lambda'_f + \Delta_\omega)^{-1} \Lambda_f \Delta_f \Phi'_f.$$

Lemma 5. Under Assumptions 1- 6, if $\frac{N^{1-\psi_f}}{\sqrt{T}} = O(1)$, if $\gamma = 0$, and $\zeta = 0$, we have,

1. $\hat{\beta}_1 = T^{-1} \mathbf{Z}' J_T \mathbf{Z} = \Lambda_f \Delta_f \Lambda'_f + \Delta_\omega + O_p(T^{-1/2})$.
2. $\hat{\beta}_2 = N^{-\psi_f} T^{-2} \mathbf{Z}' J_T \mathbf{X} J_N \mathbf{X}' J_T \mathbf{Z} = \Lambda_f \Delta_f \mathcal{P}_f \Delta_f \Lambda'_f + O_p(\Xi_{NT}^{-1})$.
3. $\hat{\beta}_3 = N^{-2\psi_f} T^{-3} \mathbf{Z}' J_T \mathbf{X} J_N \mathbf{X}' J_T \mathbf{X} J_N \mathbf{X}' J_T \mathbf{Z} = \Lambda_f \Delta_f \mathcal{P}_f \Delta_f \mathcal{P}_f \Delta_f \Lambda'_f + O_p(\Xi_{NT}^{-1})$.
4. $\hat{\beta}_4 = N^{-\psi_f} T^{-2} \mathbf{Z}' J_T \mathbf{X} J_N \mathbf{X}' J_T \mathbf{y} = \Lambda_f \Delta_f \mathcal{P}_f \Delta_f \beta_f + O_p(\Xi_{NT}^{-1})$.

Therefore,

$$\begin{aligned}
\hat{\beta} &= (T^{-1} \mathbf{Z}' \mathbf{J}_T \mathbf{Z})^{-1} N^{-\psi_f} T^{-2} \mathbf{Z}' \mathbf{J}_T \mathbf{X} \mathbf{J}_N \mathbf{X}' \mathbf{J}_T \mathbf{Z} \\
&\quad \times \left(N^{-2\psi_f} T^{-3} \mathbf{Z}' \mathbf{J}_T \mathbf{X} \mathbf{J}_N \mathbf{X}' \mathbf{J}_T \mathbf{X} \mathbf{J}_N \mathbf{X}' \mathbf{J}_T \mathbf{Z} \right)^{-1} N^{-\psi_f} T^{-2} \mathbf{Z}' \mathbf{J}_T \mathbf{X} \mathbf{J}_N \mathbf{X}' \mathbf{J}_T \mathbf{y} \\
&= \hat{\beta}_1^{-1} \hat{\beta}_2 \hat{\beta}_3^{-1} \hat{\beta}_4
\end{aligned}$$

satisfies

$$\hat{\beta} \xrightarrow[T, N \rightarrow \infty]{p} (\Lambda_f \Delta_f \Lambda_f' + \Delta_\omega)^{-1} \Lambda_f \Delta_f \mathcal{P}_f \Delta_f \Lambda_f' (\Lambda_f \Delta_f \mathcal{P}_f \Delta_f \mathcal{P}_f \Delta_f \Lambda_f')^{-1} \Lambda_f \Delta_f \mathcal{P}_f \Delta_f \beta_f.$$

Proof:

Note that $\hat{\beta}_1 = \hat{\mathbf{F}}_A$ and $\hat{\beta}_2 = \hat{\mathbf{F}}_B$ and their probability limits are established in Lemma 4.

The expressions for β_3 and β_4 are handled below.

[illegible]

$$\begin{aligned}
& + \omega' J_T \varepsilon J_N \Phi F' J_T \varepsilon J_N \Phi F' J_T F \Lambda' + \omega' J_T \varepsilon J_N \Phi F' J_T \varepsilon J_N \Phi F' J_T \omega \\
& + \omega' J_T \varepsilon J_N \Phi F' J_T \varepsilon J_N \varepsilon' J_T F \Lambda' + \omega' J_T \varepsilon J_N \Phi F' J_T \varepsilon J_N \varepsilon' J_T \omega \\
& + \omega' J_T \varepsilon J_N \varepsilon' J_T F \Phi' J_N \Phi F' J_T F \Lambda' + \omega' J_T \varepsilon J_N \varepsilon' J_T F \Phi' J_N \Phi F' J_T \omega \\
& + \omega' J_T \varepsilon J_N \varepsilon' J_T F \Phi' J_N \varepsilon' J_T F \Lambda' + \omega' J_T \varepsilon J_N \varepsilon' J_T F \Phi' J_N \varepsilon' J_T \omega \\
& = (N^{2\psi_f} T^3)^{-1} \Lambda F' J_T F \Phi' J_N \Phi F' J_T F \Phi' J_N \Phi F' J_T F \Lambda' + O_p(\Xi_{NT}^{-1}).
\end{aligned}$$

The final equality follows from Assumption 2.1, Lemmas 2 and 3 and equation A2.1. Further, note that

$$\begin{aligned}
& (N^{-2\psi_f} T^{-3}) \Lambda F' J_T F \Phi' J_N \Phi F' J_T F \Phi' J_N \Phi F' J_T F \Lambda' \\
& = \frac{1}{T} \left((N^{-\psi_f} T^{-1}) \Lambda F' J_T F \Phi' J_N \Phi F' \right) J_T \left((N^{-\psi_f} T^{-1}) \Lambda F' J_T F \Phi' J_N \Phi F' \right)' \\
& = \frac{1}{T} (\Lambda_f \Delta_f \mathcal{P}_f f' + O_p(\Xi_{NT}^{-1})) J_T (f \mathcal{P}_f \Delta_f \Lambda_f' + O_p(\Xi_{NT}^{-1})) \\
& = \Lambda_f \Delta_f \mathcal{P}_f \frac{f' J_T f}{T} \mathcal{P}_f \Delta_f \Lambda_f' + O_p(\Xi_{NT}^{-1}) \\
& = \Lambda_f \Delta_f \mathcal{P}_f \Delta_f \mathcal{P}_f \Delta_f \Lambda_f' + O_p(1/\sqrt{T}) + O_p(\Xi_{NT}^{-1}).
\end{aligned}$$

We have used the result from the proof of Lemma 4.3 in the third equality. Standard arguments, then, give us the fourth equality and the final equality follows from assumption 2.1. Hence, $\hat{\beta}_3 = N^{-2\psi_f} T^{-3} Z' J_T X J_N X' J_T X J_N X' J_T Z = \Lambda_f \Delta_f \mathcal{P}_f \Delta_f \mathcal{P}_f \Delta_f \Lambda_f' + O_p(\Xi_{NT}^{-1})$.

$$\begin{aligned}
N^{\psi_f} T^2 \hat{\beta}_4 & = \Lambda F' J_T F \Phi' J_N \Phi F' J_T F \beta + \Lambda F' J_T F \Phi' J_N \Phi F' J_T \eta + \Lambda F' J_T F \Phi' J_N \varepsilon' J_T F \beta \\
& + \Lambda F' J_T F \Phi' J_N \varepsilon' J_T \eta + \omega' J_T F \Phi' J_N \Phi F' J_T F \beta + \omega' J_T F \Phi' J_N \Phi F' J_T \eta \\
& + \omega' J_T F \Phi' J_N \varepsilon' J_T F \beta + \omega' J_T F \Phi' J_N \varepsilon' J_T \eta + \Lambda F' J_T \varepsilon J_N \Phi F' J_T F \beta \\
& + \Lambda F' J_T \varepsilon J_N \Phi F' J_T \eta + \Lambda F' J_T \varepsilon J_N \varepsilon' J_T F \beta + \Lambda F' J_T \varepsilon J_N \varepsilon' J_T \eta \\
& + \omega' J_T \varepsilon J_N \Phi F J_T F \beta + \omega' J_T \varepsilon J_N \Phi F J_T \eta + \omega' J_T \varepsilon J_N \varepsilon' J_T F \beta \\
& + \omega' J_T \varepsilon J_N \varepsilon' J_T \eta \\
& = N^{-\psi_f} T^{-2} (\Lambda F' J_T F \Phi' J_N \Phi F' J_T F \beta) + O_p(\Xi_{NT}^{-1}).
\end{aligned}$$

The final equality follows from Assumption 2.1, Lemma 2 and equation A2.1.

Further, note that, since $\mathbf{\Lambda} = \begin{bmatrix} \mathbf{\Lambda}_f & \mathbf{0} \end{bmatrix}$ (Assumption 5) and $\beta = (\beta'_f, 0')'$ (Assumption 1), we have

$$\begin{aligned}
\mathbf{\Lambda} (T^{-1} \mathbf{F}' \mathbf{J}_T \mathbf{F}) \left(N^{-\psi_f} \mathbf{\Phi}' \mathbf{J}_N \mathbf{\Phi} \right) (T^{-1} \mathbf{F}' \mathbf{J}_T \mathbf{F}) \beta &= \mathbf{\Lambda}_f (T^{-1} \mathbf{f}' \mathbf{J}_T \mathbf{f}) \left(N^{-\psi_f} \mathbf{\Phi}'_f \mathbf{J}_N \mathbf{\Phi}_f \right) (T^{-1} \mathbf{f}' \mathbf{J}_T \mathbf{f}) \beta_f \\
&\quad + \mathbf{\Lambda}_f (T^{-1} \mathbf{f}' \mathbf{J}_T \mathbf{f}) \left(N^{-\psi_f} \mathbf{\Phi}'_f \mathbf{J}_N \mathbf{\Phi}_g \right) (T^{-1} \mathbf{g}' \mathbf{J}_T \mathbf{f}) \beta_f \\
&\quad + \mathbf{\Lambda}_f (T^{-1} \mathbf{f}' \mathbf{J}_T \mathbf{g}) \left(N^{-\psi_f} \mathbf{\Phi}'_g \mathbf{J}_N \mathbf{\Phi}_f \right) (T^{-1} \mathbf{f}' \mathbf{J}_T \mathbf{f}) \beta_f \\
&\quad + \frac{N^{\psi_g - \psi_f}}{T} \mathbf{\Lambda}_f \left(T^{-1/2} \mathbf{f}' \mathbf{J}_T \mathbf{g} \right) \left(N^{-\psi_g} \mathbf{\Phi}'_g \mathbf{J}_N \mathbf{\Phi}_g \right) \\
&\quad \times \left(T^{-1/2} \mathbf{g}' \mathbf{J}_T \mathbf{f} \right) \beta_f \\
&= \mathbf{\Lambda}_f \mathbf{\Delta}_f \mathcal{P}_f \mathbf{\Delta}_f \beta_f + \mathbf{O}_p(\Xi_{NT}^{-1}).
\end{aligned}$$

The final equality follows from Assumption 2.1, 4 and Lemma 2 and equation A2.1.

Hence, $\hat{\beta}_4 = \mathbf{Z}' \mathbf{J}_T \mathbf{X} \mathbf{J}_N \mathbf{X}' \mathbf{J}_T \mathbf{y} = \mathbf{\Lambda}_f \mathbf{\Delta}_f \mathcal{P}_f \mathbf{\Delta}_f \beta_f + \mathbf{O}_p(\Xi_{NT}^{-1})$. Combining these results give the probability limit of $\hat{\beta}$ stated in Lemma 5.

Using Lemmas 1-5, we now prove Theorems 1(a), 2, 3(a) and 4(a).

Theorem 1(a) Let Assumptions 1-6 hold and $\gamma = 0$ and $\zeta = 0$. Additionally, if $\frac{N^{1-\psi_f}}{\sqrt{T}} = O(1)$, then we have,

$$\hat{y}_{t+h,f} - \mathbb{E}_t y_{t+h} = \mathbf{O}_p(\Xi_{NT}^{-1})$$

Proof: Let $\bar{\mathbf{f}} = \frac{\sum_{s=1}^T \mathbf{f}_s}{T}$. We have,

$$\begin{aligned}
\hat{y}_{t+h,f} &= \bar{y} + \left(N^{-\psi_f} T^{-1} (\mathbf{x}_t - \bar{\mathbf{x}}) \mathbf{W}_{XZ} \right) \left(N^{-2\psi_f} T^{-3} \mathbf{W}'_{XZ} \mathbf{S}_{XX} \mathbf{W}_{XZ} \right)^{-1} \left(N^{-\psi_f} T^{-2} \mathbf{W}'_{XZ} \mathbf{S}_{Xy} \right) \\
&= \beta_0 + \bar{\mathbf{f}}' \beta_f + \mathbf{O}_p(T^{-1/2}) + \left((\mathbf{f}_t - \bar{\mathbf{f}})' \mathcal{P}_f \mathbf{\Delta}_f \mathbf{\Lambda}'_f + \mathbf{O}_p(\Xi_{NT}^{-1}) \right) \\
&\quad \times \left[\mathbf{\Lambda}_f \mathbf{\Delta}_f \mathcal{P}_f \mathbf{\Delta}_f \mathcal{P}_f \mathbf{\Delta}_f \mathbf{\Lambda}'_f + \mathbf{O}_p(\Xi_{NT}^{-1}) \right]^{-1} \left(\mathbf{\Lambda}_f \mathbf{\Delta}_f \mathcal{P}_f \mathbf{\Delta}_f \beta_f + \mathbf{O}_p(\Xi_{NT}^{-1}) \right) \\
&= \beta_0 + \bar{\mathbf{f}}' \beta_f + \mathbf{O}_p(T^{-1/2}) + (\mathbf{f}_t - \bar{\mathbf{f}})' \mathcal{P}_f \mathbf{\Delta}_f \mathbf{\Lambda}'_f \left[\mathbf{\Lambda}_f \mathbf{\Delta}_f \mathcal{P}_f \mathbf{\Delta}_f \mathcal{P}_f \mathbf{\Delta}_f \mathbf{\Lambda}'_f \right]^{-1} \mathbf{\Lambda}_f \mathbf{\Delta}_f \mathcal{P}_f \mathbf{\Delta}_f \beta_f + \mathbf{O}_p(\Xi_{NT}^{-1}) \\
&= \beta_0 + \mathbf{f}'_t \mathcal{P}_f \mathbf{\Delta}_f \mathbf{\Lambda}'_f \left[\mathbf{\Lambda}_f \mathbf{\Delta}_f \mathcal{P}_f \mathbf{\Delta}_f \mathcal{P}_f \mathbf{\Delta}_f \mathbf{\Lambda}'_f \right]^{-1} \mathbf{\Lambda}_f \mathbf{\Delta}_f \mathcal{P}_f \mathbf{\Delta}_f \beta_f + \mathbf{O}_p(\Xi_{NT}^{-1}) \\
&= \beta_0 + \mathbf{f}'_t \beta_f + \mathbf{O}_p(\Xi_{NT}^{-1}) \\
&= \mathbb{E}_t y_{t+h} + \mathbf{O}_p(\Xi_{NT}^{-1}).
\end{aligned}$$

The third equality follows since, for any invertible matrices \mathbf{A} and $\mathbf{A} + \mathbf{B}$, we have:

$$(\mathbf{A} + \mathbf{B})^{-1} = \mathbf{A}^{-1} - \mathbf{A}^{-1}\mathbf{B}(\mathbf{A} + \mathbf{B})^{-1}, \quad (\text{A2.2})$$

which implies that:

$$\begin{aligned} (\Lambda_f \Delta_f \mathcal{P}_f \Delta_f \mathcal{P}_f \Delta_f \Lambda'_f + \mathbf{O}_p(\Xi_{NT}^{-1}))^{-1} &= (\Lambda_f \Delta_f \mathcal{P}_f \Delta_f \mathcal{P}_f \Delta_f \Lambda'_f)^{-1} \\ &\quad - (\Lambda_f \Delta_f \mathcal{P}_f \Delta_f \mathcal{P}_f \Delta_f \Lambda'_f)^{-1} \mathbf{O}_p(\Xi_{NT}^{-1}) \\ &\quad \times (\Lambda_f \Delta_f \mathcal{P}_f \Delta_f \mathcal{P}_f \Delta_f \Lambda'_f + \mathbf{O}_p(\Xi_{NT}^{-1}))^{-1} \\ &= (\Lambda_f \Delta_f \mathcal{P}_f \Delta_f \mathcal{P}_f \Delta_f \Lambda'_f)^{-1} - \mathbf{O}_p(1) \mathbf{O}_p(\Xi_{NT}^{-1}) \mathbf{O}_p(1) \\ &= (\Lambda_f \Delta_f \mathcal{P}_f \Delta_f \mathcal{P}_f \Delta_f \Lambda'_f)^{-1} - \mathbf{O}_p(\Xi_{NT}^{-1}). \end{aligned}$$

The final equality comes from Assumptions 4 and 5, which require Λ_f , \mathcal{P}_f , and Δ_f to be non-singular. The stochastic orders in the expression are obtained using Lemmas 4 and 5 and noting that $\frac{\sum_{s=1}^T \eta_{h+s}}{T} = O_p(T^{-1/2})$.

Theorem 2 Let $\hat{\alpha}_i$ denote the i^{th} element of $\hat{\alpha}$. Let Assumptions 1-6 hold and $\gamma = 0$ and $\zeta = 0$ and $\mathcal{P}_f = \mathbb{I}$, Then for any i ,

$$N^{\psi_f} \hat{\alpha}_i \xrightarrow[T, N \rightarrow \infty]{p} \left(\phi_{if} - N^{\psi_f-1} \bar{\phi}_f \right)' \beta_f.$$

Proof: $\hat{\alpha}_i = \mathbf{S}_i \hat{\alpha}$, where \mathbf{S}_i is the $(1 \times N)$ selector vector with i^{th} element equal to one and remaining elements zero. Using the expression for $\hat{\alpha}$ we have,

$$\begin{aligned} \hat{\alpha}_i &= N^{-\psi_f} T^{-1} \mathbf{S}_i \mathbf{J}_N \mathbf{X}' \mathbf{J}_T \mathbf{Z} \left(N^{-2\psi_f} T^{-3} \mathbf{Z}' \mathbf{J}_T \mathbf{X} \mathbf{J}_N \mathbf{X}' \mathbf{J}_T \mathbf{X} \mathbf{J}_N \mathbf{X}' \mathbf{J}_T \mathbf{Z} \right)^{-1} \\ &\quad \times N^{-\psi_f} T^{-2} \mathbf{Z}' \mathbf{J}_T \mathbf{X} \mathbf{J}_N \mathbf{X}' \mathbf{J}_T \mathbf{y}. \end{aligned}$$

From Lemma 4 and 5, we have

$$\hat{\alpha}_i = N^{-\psi_f} \mathbf{S}_i \mathbf{J}_N \phi_f \Delta_f \Lambda'_f (\Lambda_f \Delta_f \mathcal{P}_f \Delta_f \mathcal{P}_f \Delta_f \Lambda'_f)^{-1} \Lambda_f \Delta_f \mathcal{P}_f \Delta_f \beta_f + o_p(1).$$

The expression $\mathbf{S}_i \mathbf{J}_N \Phi_f$ has the probability limit $\phi_{if} - N^{\psi_f-1} \bar{\phi}_f$ as $N, T \rightarrow \infty$. Therefore,

we have that

$$N^{\psi_f} \hat{\alpha}_i \xrightarrow[T, N \rightarrow \infty]{p} \left(\phi_{if} - N^{\psi_f-1} \overline{\phi_f} \right)' \Delta_f \Lambda'_f (\Lambda_f \Delta_f \mathcal{P}_f \Delta_f \mathcal{P}_f \Delta_f \Lambda'_f)^{-1} \Lambda_f \Delta_f \mathcal{P}_f \Delta_f \beta_f.$$

Using the fact that $\mathcal{P}_f = \mathbb{I}$ this reduces to $(\phi_{if} - N^{\psi_f-1} \overline{\phi_f})' \beta_f$.

Define $\mathbf{G}_\beta \equiv \hat{\beta}_1^{-1} \hat{\beta}_2 (\Lambda_f \Delta_f \mathcal{P}_f \Delta_f \mathcal{P}_f \Delta_f \Lambda'_f)^{-1} (\Lambda_f \Delta_f \mathcal{P}_f \Delta_f)$, where $\hat{\beta}_1$ and $\hat{\beta}_2$ are defined in Lemma 5.

Theorem 3(a) Let Assumptions 1-6 hold and $\gamma = 0$ and $\zeta = 0$. Additionally, if $\frac{N^{1-\psi_f}}{\sqrt{T}} = O(1)$, then we have,

$$\hat{\beta} - \mathbf{G}_\beta \beta_f = O_p(\Xi_{NT}^{-1}).$$

Proof:

$$\begin{aligned} \hat{\beta} &= (T^{-1} \mathbf{Z}' \mathbf{J}_T \mathbf{Z})^{-1} N^{-\psi_f} T^{-2} \mathbf{Z}' \mathbf{J}_T \mathbf{X} \mathbf{J}_N \mathbf{X}' \mathbf{J}_T \mathbf{Z} \\ &\quad \times \left(N^{-2\psi_f} T^{-3} \mathbf{Z}' \mathbf{J}_T \mathbf{X} \mathbf{J}_N \mathbf{X}' \mathbf{J}_T \mathbf{X} \mathbf{J}_N \mathbf{X}' \mathbf{J}_T \mathbf{Z} \right)^{-1} N^{-\psi_f} T^{-2} \mathbf{Z}' \mathbf{J}_T \mathbf{X} \mathbf{J}_N \mathbf{X}' \mathbf{J}_T \mathbf{y} \\ &= \hat{\beta}_1^{-1} \hat{\beta}_2 (\Lambda_f \Delta_f \mathcal{P}_f \Delta_f \mathcal{P}_f \Delta_f \Lambda'_f + O_p(\Xi_{NT}^{-1}))^{-1} (\Lambda_f \Delta_f \mathcal{P}_f \Delta_f \beta_f + O_p(\Xi_{NT}^{-1})) \\ &= \hat{\beta}_1^{-1} \hat{\beta}_2 (\Lambda_f \Delta_f \mathcal{P}_f \Delta_f \mathcal{P}_f \Delta_f \Lambda'_f)^{-1} (\Lambda_f \Delta_f \mathcal{P}_f \Delta_f) \beta_f + O_p(\Xi_{NT}^{-1}) \\ &= \mathbf{G}_\beta \beta_f + O_p(\Xi_{NT}^{-1}). \end{aligned}$$

The stochastic orders in the expression are obtained using Lemmas 4 and 5. The second equality follows by employing the identity for the inverse of a sum of two matrices as in the proof of Theorem 1(a).

Define $\mathbf{H}_f \equiv \hat{\mathbf{F}}_A \hat{\mathbf{F}}_B^{-1} \Lambda_f \Delta_f \mathcal{P}_f$ and $\mathbf{H}_0 \equiv \hat{\mathbf{F}}_A \hat{\mathbf{F}}_B^{-1} [N^{-\psi_f} T^{-1} \mathbf{Z}' \mathbf{J}_T \mathbf{X} \mathbf{J}_N \phi_0]$.

Theorem 4(a) Let Assumptions 1-6 hold and $\gamma = 0$ and $\zeta = 0$. Additionally, if $\frac{N^{1-\psi_f}}{\sqrt{T}} = O(1)$, we have,

$$\hat{\mathbf{F}}_t - (\mathbf{H}_0 + \mathbf{H}_f \mathbf{f}_t) = O_p(\Xi_{NT}^{-1}).$$

Proof:

$$\begin{aligned}
\hat{\mathbf{F}}_t &= T^{-1} \mathbf{Z}' \mathbf{J}_T \mathbf{Z} \left(N^{-\psi_f} T^{-2} \mathbf{Z}' \mathbf{J}_T \mathbf{X} \mathbf{J}_N \mathbf{X}' \mathbf{J}_T \mathbf{Z} \right)^{-1} N^{-\psi_f} T^{-1} \mathbf{Z}' \mathbf{J}_T \mathbf{X} \mathbf{J}_N \mathbf{x}_t \\
&= \hat{\mathbf{F}}_A \hat{\mathbf{F}}_B^{-1} \left[N^{-\psi_f} T^{-1} \mathbf{Z}' \mathbf{J}_T \mathbf{X} \mathbf{J}_N \phi_0 + \Lambda_f \Delta_f \mathcal{P}_f \mathbf{f}_t + \mathcal{O}_p(\Xi_{NT}^{-1}) \right] \\
&= \hat{\mathbf{F}}_A \hat{\mathbf{F}}_B^{-1} \left[N^{-\psi_f} T^{-1} \mathbf{Z}' \mathbf{J}_T \mathbf{X} \mathbf{J}_N \phi_0 \right] + \hat{\mathbf{F}}_A \hat{\mathbf{F}}_B^{-1} \Lambda_f \Delta_f \mathcal{P}_f \mathbf{f}_t + \mathcal{O}_p(\Xi_{NT}^{-1}) \\
&= \mathbf{H}_0 + \mathbf{H}_f \mathbf{f}_t + \mathcal{O}_p(\Xi_{NT}^{-1}).
\end{aligned}$$

Second equality follows from employing the expression for $\hat{\mathbf{F}}_{c,t}$ in Lemma 4. $\mathbf{H}_f' \mathbf{G}_\beta = \mathbf{I}$ can be verified easily given Assumptions 4 and 5.

Remark 7. The proofs of Theorem 1, 2, and 4 can be approached in an alternative manner. We can demonstrate that, for the matrix $\mathbf{H}_2 = \mathbf{Z}' \mathbf{J}_T \mathbf{X} \mathbf{J}_N \Phi_f$, $\hat{\mathbf{F}}_t$ converges to $\mathbf{H}_2 \mathbf{f}_t$ at the rate Ξ_{NT} , while $\hat{\beta}$ converges to $\mathbf{H}_2'^{-1} \beta$ at $\min(\sqrt{N^{\psi_f}}, \sqrt{T})$ rate, under the assumptions of our model. Therefore, by specifying a different limit, we can establish faster convergence of $\hat{\beta}$ to that limit. Essentially, we require that rotations in $\hat{\mathbf{F}}_t$ and $\hat{\beta}$ be nullified upon multiplication, which occurs with this newly specified limit.

However, we specify the matrix \mathbf{H}_f such that $\hat{\beta}$ converges to $\mathbf{H}_f'^{-1} \beta$ at the slower Ξ_{NT} rate. We do this for simplicity of exposition, noting that the convergence rate of the target depends on the convergence rates of both $\hat{\mathbf{F}}_t$ and $\hat{\beta}$. Consequently, any improvement in the convergence result for $\hat{\beta}$ is not useful unless the rate for $\hat{\mathbf{F}}_t$ improves as well.

In Kelly & Pruitt [2015], they specify the convergence of $\hat{\mathbf{F}}_t$ to $\mathbf{H} \mathbf{F}_t$, where $\mathbf{H} = \mathbf{Z}' \mathbf{J}_T \mathbf{X} \mathbf{J}_N \Phi$ at a \sqrt{N} rate. In our weak factor context, this would be a $\sqrt{N^{\psi_f}}$ rate. However, this matrix \mathbf{H} is not square unless there are zero irrelevant factors. Elements of $\mathbf{H} \mathbf{F}_t$ are linear combinations of relevant and irrelevant factors. Therefore, their convergence result can not be employed in our context to obtain faster convergence for the target estimator. We must establish convergence of our factor estimates to some rotation of relevant factors.

A3 Proofs of Theorems 1(b), 3(b) and 4(b)

We introduce 3 Lemmas which shall be employed for subsequent proofs (Theorems 1(b), 3(b), 4(b)) which deal with the general setting of $\zeta \neq 0$ and $\gamma \neq 0$.

Lemma 6. Let Assumptions 1-3 , 6, 8 and 9 hold. Additionally, let $\frac{T}{N} = O(1)$. Then,

1. $N^{-1}T^{-1/2}\boldsymbol{\varepsilon}'\mathbf{J}_T\boldsymbol{\varepsilon}\mathbf{J}_N\boldsymbol{\varepsilon}_t = O_p(\delta_{NT}^{-1})$.
2. $N^{-1}T^{-3/2}\boldsymbol{\varepsilon}'\mathbf{J}_T\boldsymbol{\varepsilon}\mathbf{J}_N\boldsymbol{\varepsilon}'\mathbf{J}_T\boldsymbol{\varepsilon} = O_p(\delta_{NT}^{-1})$.
3. $N^{-1}T^{-3/2}\mathbf{F}'\mathbf{J}_T\boldsymbol{\varepsilon}\mathbf{J}_N\boldsymbol{\varepsilon}'\mathbf{J}_T\boldsymbol{\varepsilon} = O_p(\delta_{NT}^{-1})$.
4. $N^{-\psi_f/2}T^{-1}\boldsymbol{\Phi}'\mathbf{J}_N\boldsymbol{\varepsilon}'\mathbf{J}_T\boldsymbol{\varepsilon} = O_p(\Xi_{NT}^{-1})$.
5. $N^{-1}T^{-3/2}\boldsymbol{\omega}'\mathbf{J}_T\boldsymbol{\varepsilon}\mathbf{J}_N\boldsymbol{\varepsilon}'\mathbf{J}_T\boldsymbol{\varepsilon} = O_p(\delta_{NT}^{-1})$.
6. $N^{-1}T^{-3/2}\boldsymbol{\eta}'\mathbf{J}_T\boldsymbol{\varepsilon}\mathbf{J}_N\boldsymbol{\varepsilon}'\mathbf{J}_T\boldsymbol{\varepsilon} = O_p(\delta_{NT}^{-1})$.
7. (a) $T^{-1/2}\mathbf{F}'\mathbf{J}_T\boldsymbol{\varepsilon} = O_p(1)$ and $T^{-1/2}\boldsymbol{\omega}'\mathbf{J}_T\boldsymbol{\varepsilon} = O_p(1)$.

To prove this lemma, we need to show the following,

Let Assumptions 1-3 and 6-8 hold. Then, for all t, m ,

$$N^{-1}T^{-1/2}\sum_{i,s}\varepsilon_s(m)\varepsilon_{is}\varepsilon_{it} = O_p(\delta_{NT}^{-1}).$$

Proof: Adding and subtracting terms, we can write the above as,

$$\begin{aligned} & N^{-1/2}\left(N^{-1/2}T^{-1/2}\sum_{i,s}\varepsilon_s(m)[\varepsilon_{is}\varepsilon_{it} - \sigma_{ii,st}]\right) + T^{-1/2}\left(N^{-1}\sum_{i,s}\varepsilon_s(m)\sigma_{ii,st}\right). \\ & = I + II \end{aligned}$$

$$\mathbb{E}\left|N^{-1}\sum_{i,s}\varepsilon_s(m)\sigma_{ii,st}\right| \leq N^{-1}\max_s\mathbb{E}|\varepsilon_s(m)|\sum_{i,s}|\sigma_{ii,st}| = O_p(1) \text{ by Assumption 3.1 2.3.}$$

Hence, the second term is $O_p(T^{-1/2})$.

For the first term to be $O_p(N^{-1/2})$, it is sufficient to show that

$$\mathbb{E}\left|(NT)^{-1/2}\sum_{i,s}\varepsilon_s(m)[\varepsilon_{is}\varepsilon_{it} - \sigma_{ii,st}]\right|^2 \leq M$$

Proof: Using Cauchy Schwartz inequality twice,

$$\begin{aligned}
& \mathbb{E} \left| (NT)^{-1/2} \sum_{i,s} \varepsilon_s(m) [\varepsilon_{is}\varepsilon_{it} - \sigma_{ii,st}] \right|^2 \\
&= \mathbb{E} \left[(NT)^{-1} \sum_{i,j,s,u} \varepsilon_s(m)\varepsilon_u(m) [\varepsilon_{is}\varepsilon_{it} - \sigma_{ii,st}] [\varepsilon_{ju}\varepsilon_{jt} - \sigma_{jj,ut}] \right] \\
&\leq \max_{s,u} \left(\mathbb{E} |\varepsilon_s(m)\varepsilon_u(m)|^2 \right)^{1/2} \\
&\quad \times \left(\mathbb{E} \left[(NT)^{-1} \sum_{i,j,s,u} [\varepsilon_{is}\varepsilon_{it} - \sigma_{ii,st}] [\varepsilon_{ju}\varepsilon_{jt} - \sigma_{jj,ut}] \right]^2 \right)^{1/2} \\
&\leq \max_{s,u} \left(\mathbb{E} |\varepsilon_s(m)|^4 \right)^{1/4} \left(\mathbb{E} |\varepsilon_u(m)|^4 \right)^{1/4} \left(\mathbb{E} \left| (NT)^{-1/2} \sum_{i,s} [\varepsilon_{is}\varepsilon_{it} - \sigma_{ii,st}] \right|^4 \right)^{1/2} < \infty
\end{aligned}$$

by Assumptions 2.3 and 3.2. Therefore we have that,

$$N^{-1}T^{-1/2} \sum_{i,s} \varepsilon_s(m)\varepsilon_{is}\varepsilon_{it} = O_p(\delta_{NT}^{-1}). \quad (\text{A3.1})$$

Now we can prove Lemma 6

Item 1 = $N^{-1}T^{-1/2}\varepsilon' \mathbf{J}_T \varepsilon \mathbf{J}_N \varepsilon_t$ has generic m^{th} element given by

$$\begin{aligned}
& N^{-1}T^{-1/2} \sum_{i,s} \varepsilon_s(m)\varepsilon_{is}\varepsilon_{it} - N^{-2}T^{-1/2} \sum_{i,j,s} \varepsilon_s(m)\varepsilon_{is}\varepsilon_{jt} \\
& - N^{-1}T^{-3/2} \sum_{i,s,u} \varepsilon_s(m)\varepsilon_{iu}\varepsilon_{it} + N^{-2}T^{-3/2} \sum_{i,j,s,u} \varepsilon_s(m)\varepsilon_{iu}\varepsilon_{jt} \\
& = 1.\text{I} - 1.\text{II} - 1.\text{III} + 1.\text{IV}
\end{aligned}$$

1.I is $O_p(\delta_{NT}^{-1})$ by equation A3.1.

$$\begin{aligned}
1.\text{II} &= N^{-1/2} \left(N^{-1} \sum_{i \in \Delta_{m,\varepsilon}} \left(T^{-1/2} \sum_s \varepsilon_s(m)\varepsilon_{is} \right) + \frac{T^{1/2}}{N} \sum_{i \in \Delta_{m,\varepsilon}^c} \left(T^{-1} \sum_s \varepsilon_s(m)\varepsilon_{is} \right) \right) \left(N^{-1/2} \sum_j \varepsilon_{jt} \right) \\
&= N^{-1/2} O_p(1) \\
&= O_p(N^{-1/2})
\end{aligned}$$

by Assumption 8 and Lemma 1.3.

1.III is $O_p(\delta_{NT}^{-1}T^{-1/2})$ by Lemma 1.3 and 1.10.

1.IV is $O_p(N^{-1}T^{-1/2})$ by Lemma 1.3. Summing these terms, Item 1 is $O_p(\delta_{NT}^{-1})$.

Item 2 : $N^{-1}T^{-3/2}\boldsymbol{\varepsilon}'\mathbf{J}_T\boldsymbol{\varepsilon}\mathbf{J}_N\boldsymbol{\varepsilon}'\mathbf{J}_T\boldsymbol{\varepsilon}$ is a $N \times N$ matrix with generic (m_1, m_2) element,

$$\begin{aligned}
& N^{-1}T^{-3/2} \sum_{i,s,t} \varepsilon_s(m_1) \varepsilon_{is} \varepsilon_{it} \varepsilon_t(m_2) - N^{-1}T^{-5/2} \sum_{i,s,t,u} \varepsilon_s(m_1) \varepsilon_{is} \varepsilon_{it} \varepsilon_u(m_2) \\
& - N^{-1}T^{-5/2} \sum_{i,s,t,u} \varepsilon_s(m_1) \varepsilon_{it} \varepsilon_{iu} \varepsilon_u(m_2) + N^{-1}T^{-7/2} \sum_{i,s,t,u,v} \varepsilon_s(m_1) \varepsilon_{it} \varepsilon_{iu} \varepsilon_v(m_2) \\
& + N^{-2}T^{-3/2} \sum_{i,j,s,t} \varepsilon_s(m_1) \varepsilon_{is} \varepsilon_{jt} \varepsilon_t(m_2) + N^{-2}T^{-5/2} \sum_{i,j,s,t,u} \varepsilon_s(m_1) \varepsilon_{is} \varepsilon_{jt} \varepsilon_u(m_2) \\
& + N^{-2}T^{-5/2} \sum_{i,j,s,t,u} \varepsilon_s(m_1) \varepsilon_{it} \varepsilon_{ju} \varepsilon_u(m_2) - N^{-2}T^{-7/2} \sum_{i,j,s,t,u,v} \varepsilon_s(m_1) \varepsilon_{it} \varepsilon_{ju} \varepsilon_v(m_2) \\
& = 2.I - \dots - 2.VIII.
\end{aligned}$$

2.I can be written as,

$$\begin{aligned}
& T^{-1/2} \left(N^{-1} \left[\sum_{i \in (\Delta_{m_1, \varepsilon} \cup \Delta_{m_2, \varepsilon})} \left(T^{-1/2} \sum_s \varepsilon_s(m_1) \varepsilon_{is} \right) \left(T^{-1/2} \sum_t \varepsilon_t(m_2) \varepsilon_{it} \right) \right] \right. \\
& \left. + \frac{T}{N} \left[\sum_{i \in (\Delta_{m_1, \varepsilon} \cup \Delta_{m_2, \varepsilon})^c} \left(T^{-1} \sum_s \varepsilon_s(m_1) \varepsilon_{is} \right) \left(T^{-1} \sum_t \varepsilon_t(m_2) \varepsilon_{it} \right) \right] \right) \\
& = O_p(T^{-1/2}),
\end{aligned}$$

by Assumption 8, given that $\frac{T}{N} = O(1)$.

2.II is $O_p(\delta_{NT}^{-1}T^{-1/2})$ by Lemma 1.3 and equation A3.1. Item 2.III is identical.

2.IV is $O_p(\delta_{NT}^{-1}T^{-1})$ by Lemma 1.3 and 1.10.

2.V can be written as,

$$\begin{aligned}
& T^{-1/2} \left(\left[N^{-1} \sum_{i \in \Delta_{m_1, \varepsilon}} \left(T^{-1/2} \sum_s \varepsilon_s(m_1) \varepsilon_{is} \right) + \frac{T^{1/2}}{N} \sum_{i \in \Delta_{m_1, \varepsilon}^c} \left(T^{-1} \sum_s \varepsilon_s(m_1) \varepsilon_{is} \right) \right] \right. \\
& \left. \times \left[N^{-1} \sum_{j \in \Delta_{m_2, \varepsilon}} \left(T^{-1/2} \sum_t \varepsilon_t(m_2) \varepsilon_{jt} \right) + \frac{T^{1/2}}{N} \sum_{j \in \Delta_{m_2, \varepsilon}^c} \left(T^{-1} \sum_t \varepsilon_t(m_2) \varepsilon_{jt} \right) \right] \right).
\end{aligned}$$

This is $O_p(T^{-1/2})$ by Assumption 8, given that $\frac{T^{1/2}}{N} = O(1)$.

2.VI is given by

$$\begin{aligned}
& N^{-1/2}T^{-1} \left(N^{-1} \sum_{i \in \Delta_{m_1, \varepsilon}} \left(T^{-1/2} \sum_s \varepsilon_s(m_1) \varepsilon_{is} \right) + \frac{T^{1/2}}{N} \sum_{i \in \Delta_{m_1, \varepsilon}^c} \left(T^{-1} \sum_s \varepsilon_s(m_1) \varepsilon_{is} \right) \right) \\
& \times \left(N^{-1/2}T^{-1/2} \sum_{j,t} \varepsilon_{jt} \right) \left(T^{-1/2} \sum_v \varepsilon_v(m_2) \right) \\
& = O_p \left(N^{-1/2}T^{-1} \right)
\end{aligned}$$

by Assumption 8 and Lemma 1.3. Item 2.VII is identical.

2.VIII is $O_p \left(N^{-1}T^{-3/2} \right)$ by Lemma 1.3.

Summing these terms, Item 2 is $O_p \left(\delta_{NT}^{-1} \right)$.

Item 3 = $N^{-1}T^{-3/2} \mathbf{F}' \mathbf{J}_T \varepsilon \mathbf{J}_N \varepsilon' \mathbf{J}_T \varepsilon = O_p \left(\delta_{NT}^{-1} \right)$ is a $K \times N$ matrix with generic (m_1, m_2) element

$$\begin{aligned}
& N^{-1}T^{-3/2} \sum_{i,s,t} F_s(m_1) \varepsilon_{is} \varepsilon_{it} \varepsilon_t(m_2) - N^{-1}T^{-5/2} \sum_{i,s,t,u} F_s(m_1) \varepsilon_{is} \varepsilon_{it} \varepsilon_u(m_2) \\
& - N^{-1}T^{-5/2} \sum_{i,s,t,u} F_s(m_1) \varepsilon_{it} \varepsilon_{iu} \varepsilon_u(m_2) + N^{-1}T^{-7/2} \sum_{i,s,t,u,v} F_s(m_1) \varepsilon_{it} \varepsilon_{iu} \varepsilon_v(m_2) \\
& + N^{-2}T^{-3/2} \sum_{i,j,s,t} F_s(m_1) \varepsilon_{is} \varepsilon_{jt} \varepsilon_t(m_2) + N^{-2}T^{-5/2} \sum_{i,j,s,t,u} F_s(m_1) \varepsilon_{is} \varepsilon_{jt} \varepsilon_u(m_2) \\
& + N^{-2}T^{-5/2} \sum_{i,j,s,t,u} F_s(m_1) \varepsilon_{it} \varepsilon_{ju} \varepsilon_u(m_2) - N^{-2}T^{-7/2} \sum_{i,j,s,t,u,v} F_s(m_1) \varepsilon_{it} \varepsilon_{ju} \varepsilon_v(m_2) \\
& = 3.I - \dots - 3.VIII.
\end{aligned}$$

3.I can be written as,

$$\begin{aligned}
& T^{-1/2} \left(N^{-1} \left[\sum_{i \in \Delta_{m_2, \varepsilon}} \left(T^{-1/2} \sum_s F_s(m_1) \varepsilon_{is} \right) \left(T^{-1/2} \sum_t \varepsilon_t(m_2) \varepsilon_{it} \right) \right] \right. \\
& \left. + \frac{T^{1/2}}{N} \left[\sum_{i \in \Delta_{m_2, \varepsilon}^c} \left(T^{-1/2} \sum_s F_s(m_1) \varepsilon_{is} \right) \left(T^{-1} \sum_t \varepsilon_t(m_2) \varepsilon_{it} \right) \right] \right) \\
& = O_p(T^{-1/2})
\end{aligned}$$

by Assumptions 3.6, 8 and the fact that $\frac{T^{1/2}}{N} = O(1)$.

3.II = $O_p \left(\delta_{NT}^{-1} T^{-1/2} \right)$ by Lemma 1.3 and 1.12.

3.III = $O_p(\delta_{NT}^{-1})$ by 2.1 and equation A3.1.

3.IV = $O_p(\delta_{NT}^{-1}T^{-1/2})$ by Assumption 2.1, Lemma 1.3 and 1.10.

3.V can be written as,

$$\begin{aligned} & T^{-1/2} \left(\left[N^{-1} \sum_i \left(T^{-1/2} \sum_s F_s(m_1) \varepsilon_{is} \right) \right] \right. \\ & \quad \times \left. \left[N^{-1} \sum_{i \in \Delta_{m_2, \varepsilon}} \left(T^{-1/2} \sum_t \varepsilon_t(m_2) \varepsilon_{jt} \right) + \frac{T^{1/2}}{N} \sum_{i \in \Delta_{m_2, \varepsilon}^c} \left(T^{-1} \sum_t \varepsilon_t(m_2) \varepsilon_{jt} \right) \right] \right) \\ & = O_p(T^{-1/2}) \end{aligned}$$

by Assumption 3.6, given that $\frac{T^{1/2}}{N} = O(1)$.

3.VI is given by

$$\begin{aligned} & N^{-1/2}T^{-1} \left(\left[N^{-1} \sum_i \left(T^{-1/2} \sum_s F_s(m_1) \varepsilon_{is} \right) \right] \right. \\ & \quad \times \left. \left(N^{-1/2}T^{-1/2} \sum_{j,t} \varepsilon_{jt} \right) \left(T^{-1/2} \sum_u \varepsilon_u(m_2) \right) \right) \\ & = O_p(N^{-1/2}T^{-1}) \end{aligned}$$

by Assumption 3.6 and Lemma 1.3.

3.VII is given by

$$\begin{aligned} & N^{-1/2}T^{-1} \left(\left(T^{-1} \sum_s F_s(m_2) \right) \left(N^{-1/2}T^{-1/2} \sum_{i,t} \varepsilon_{it} \right) \right. \\ & \quad \times \left. \left[N^{-1} \sum_{j \in \Delta_{m_2, \varepsilon}} \left(T^{-1/2} \sum_u \varepsilon_u(m_2) \varepsilon_{ju} \right) + \frac{T^{1/2}}{N} \sum_{j \in \Delta_{m_2, \varepsilon}^c} \left(T^{-1} \sum_u \varepsilon_u(m_2) \varepsilon_{ju} \right) \right] \right) \\ & = O_p(N^{-1/2}T^{-1}) \end{aligned}$$

by Assumption 8 and 2.1.

3.VIII is $O_p(N^{-1}T^{-1})$ by Assumption 2.1 and Lemma 1.3. Summing these terms, Item 3 is

$$O_p(\delta_{NT}^{-1}).$$

Item 5 and Item 6 follow similar steps as 3.

Item 4 is a $K \times N$ matrix which can be partitioned as

$$N^{-\psi_f/2}T^{-1}\Phi'_f\mathbf{J}_N\boldsymbol{\varepsilon}'\mathbf{J}_T\boldsymbol{\varepsilon} = \begin{bmatrix} N^{-\psi_f/2}T^{-1}\Phi'_f\mathbf{J}_N\boldsymbol{\varepsilon}'\mathbf{J}_T\boldsymbol{\varepsilon} \\ N^{-\psi_f/2}T^{-1}\Phi'_g\mathbf{J}_N\boldsymbol{\varepsilon}'\mathbf{J}_T\boldsymbol{\varepsilon} \end{bmatrix}.$$

We show that $N^{-\psi_f/2}T^{-1}\Phi'_f\mathbf{J}_N\boldsymbol{\varepsilon}'\mathbf{J}_T\boldsymbol{\varepsilon}$ is $\mathcal{O}_p(\Gamma_{N_fT}^{-1})$. Similar arguments would establish $N^{-\psi_g/2}T^{-1}\Phi'_g\mathbf{J}_N\boldsymbol{\varepsilon}'\mathbf{J}_T\boldsymbol{\varepsilon}$ is $\mathcal{O}_p(\Gamma_{N_gT}^{-1})$, which implies $N^{-\psi_f/2}T^{-1}\Phi'_g\mathbf{J}_N\boldsymbol{\varepsilon}'\mathbf{J}_T\boldsymbol{\varepsilon}$ is $\mathcal{O}_p\left(\frac{N^{\psi_g-\psi_f}}{\Gamma_{N_gT}}\right)$.

Hence the matrix $N^{-\psi_f/2}T^{-1}\Phi'_f\mathbf{J}_N\boldsymbol{\varepsilon}'\mathbf{J}_T\boldsymbol{\varepsilon}$ is $\mathcal{O}_p\left(\Gamma_{N_fT} \vee \frac{N^{\psi_g-\psi_f}}{\Gamma_{N_gT}}\right) = \mathcal{O}_p(\Xi_{NT}^{-1})$.

Below, we show that $N^{-\psi_f/2}T^{-1}\Phi'_f\mathbf{J}_N\boldsymbol{\varepsilon}'\mathbf{J}_T\boldsymbol{\varepsilon}$ is $\mathcal{O}_p(\Gamma_{N_fT}^{-1})$.

$N^{-\psi_f/2}T^{-1}\Phi'_f\mathbf{J}_N\boldsymbol{\varepsilon}'\mathbf{J}_T\boldsymbol{\varepsilon}$ is a $K_g \times N$ matrix with generic (m_1, m_2) element

$$\begin{aligned} & N^{-\psi_f/2}T^{-1} \sum_{i,t} \phi_{if}(m_1) \varepsilon_t(m_2) \varepsilon_{it} - N^{-\psi_f/2-1}T^{-1} \sum_{i,j,t} \phi_{if}(m_1) \varepsilon_t(m_2) \varepsilon_{jt} \\ & - N^{-\psi_f/2}T^{-2} \sum_{j,s,t} \varepsilon_s(m_2) \phi_{jf}(m_1) \varepsilon_{jt} + N^{-\psi_f/2-1}T^{-2} \sum_{i,j,s,t} \varepsilon_s(m_2) \phi_{if}(m_1) \varepsilon_{jt} \\ & = 4.I - 4.II - 4.III + 4.IV. \end{aligned}$$

4.I is $\mathcal{O}_p(\Gamma_{N_fT}^{-1})$ by Lemma 1.16.

4.II is $N^{\psi_f/2}T^{-1/2}\delta_{NT}^{-1}\left(N^{-1}T^{-1/2}\sum_{j,t}\varepsilon_t(m_2)\varepsilon_{jt}\right)(N^{-\psi_f}\phi_{if}(m_1))$ which is $\mathcal{O}_p(N^{\psi_f/2}T^{-1/2}\delta_{NT}^{-1})$

by Assumption 2.2 and Lemma 1.10. If $\frac{N^{\psi_f}}{T} = O(1)$ then this is $\mathcal{O}_p(\Gamma_{N_fT}^{-1})$.

4.III is $T^{-1/2}\left(T^{-1}\sum_t\left(\sum_j N^{-\psi_f/2}\phi_{jf}(m_1)\varepsilon_{jt}\right)\right)(T^{-1/2}\sum_s\varepsilon_s(m_2))$, which is

$\mathcal{O}_p(T^{-1/2})$ by Assumption 3.7 and Lemma 1.3.

4.IV is equal to $(N^{\frac{\psi_f-1}{2}}T^{-1}(N^{-\psi_f}\sum_i\phi_{if}(m_1))\left(N^{-1/2}T^{-1/2}\sum_{j,t}\varepsilon_{jt}\right)(T^{-1/2}\sum_s\varepsilon_s(m_2))$

which is $\mathcal{O}_p\left(N^{\frac{\psi_f-1}{2}}T^{-1}\right)$ by Assumption 2.2 and Lemma 1.3.

Summing these terms, $N^{-\psi_f/2}T^{-1}\Phi'_f\mathbf{J}_N\boldsymbol{\varepsilon}'\mathbf{J}_T\boldsymbol{\varepsilon}$ is $\mathcal{O}_p(\Gamma_{N_fT}^{-1})$ and hence $N^{-\psi_f/2}T^{-1}\Phi'_f\mathbf{J}_N\boldsymbol{\varepsilon}'\mathbf{J}_T\boldsymbol{\varepsilon}$

is $\mathcal{O}_p\left(\Gamma_{N_fT} \vee \frac{N^{\psi_g-\psi_f}}{\Gamma_{N_gT}}\right) = \mathcal{O}_p(\Xi_{NT}^{-1})$.

Item 7:

(a)

$$\begin{aligned} T^{-1/2}\mathbf{F}'\mathbf{J}_T\boldsymbol{\varepsilon} &= T^{-1/2}\sum_t\mathbf{F}_t\boldsymbol{\varepsilon}'_t - \left(T^{-1}\sum_t\mathbf{F}_t\right)\left(T^{-1/2}\sum_t\boldsymbol{\varepsilon}'_t\right) \\ &= \mathcal{O}_p(1) \end{aligned}$$

by Assumption 2.1, 3.6 and Lemma 1.3. 7(b) follows using the same argument and employing Assumption 2.4, 3.5, and Lemma 1.3.

Lemma 7. *Under Assumptions 1-5, 8 and 9, if $\frac{N^{1-\psi_f}}{\sqrt{T}} = O(1)$ and $\frac{T}{N} = O(1)$, we have,*

1. $\hat{\mathbf{F}}_A = T^{-1} \mathbf{Z}' \mathbf{J}_T \mathbf{Z} = \mathbf{\Lambda}_f \mathbf{\Delta}_f \mathbf{\Lambda}'_f + \zeta (T^{-1} \mathbf{\varepsilon}' \mathbf{J}_T \mathbf{\varepsilon}) \zeta' + \mathbf{\Delta}_\omega + O_p(T^{-1/2}).$
2. $\hat{\mathbf{F}}_B = N^{-\psi_f} T^{-2} \mathbf{Z}' \mathbf{J}_T \mathbf{X} \mathbf{J}_N \mathbf{X}' \mathbf{J}_T \mathbf{Z} = \mathbf{\Lambda}_f \mathbf{\Delta}_f \mathcal{P}_f \mathbf{\Delta}_f \mathbf{\Lambda}'_f + O_p(\Xi_{NT}^{-1}).$
3. $\hat{\mathbf{F}}_{C,t} = N^{-\psi_f} T^{-1} \mathbf{Z}' \mathbf{J}_T \mathbf{X} \mathbf{J}_N \mathbf{x}_t = N^{-\psi_f} T^{-1} \mathbf{Z}' \mathbf{J}_T \mathbf{X} \mathbf{J}_N \phi_0 + \mathbf{\Lambda}_f \mathbf{\Delta}_f \mathcal{P}_f \mathbf{f}_t + O_p(\Xi_{NT}^{-1}).$

Consequently, the probability limit of $\hat{\mathbf{F}}_t$ is

$$\hat{\mathbf{F}}_t \xrightarrow[T, N \rightarrow \infty]{p} (\mathbf{\Lambda}_f \mathbf{\Delta}_f \mathbf{\Lambda}'_f + \zeta (T^{-1} \mathbf{\varepsilon}' \mathbf{J}_T \mathbf{\varepsilon}) \zeta' + \mathbf{\Delta}_\omega) (\mathbf{\Lambda}_f \mathbf{\Delta}_f \mathcal{P}_f \mathbf{\Delta}_f \mathbf{\Lambda}'_f)^{-1} (N^{-\psi_f} T^{-1} \mathbf{Z}' \mathbf{J}_T \mathbf{X} \mathbf{J}_N \phi_0 + \mathbf{\Lambda}_f \mathbf{\Delta}_f \mathcal{P}_f \mathbf{f}_t)$$

Proof:

$$\begin{aligned} \hat{\mathbf{F}}_t &= T^{-1} \mathbf{Z}' \mathbf{J}_T \mathbf{Z} \left(N^{-\psi} T^{-2} \mathbf{Z}' \mathbf{J}_T \mathbf{X} \mathbf{J}_N \mathbf{X}' \mathbf{J}_T \mathbf{Z} \right)^{-1} N^{-\psi} T^{-1} \mathbf{Z}' \mathbf{J}_T \mathbf{X} \mathbf{J}_N \mathbf{x}_t \\ &= \hat{\mathbf{F}}_A \hat{\mathbf{F}}_B^{-1} \hat{\mathbf{F}}_{C,t}. \end{aligned}$$

We look at all these terms separately,

$$\begin{aligned} \hat{\mathbf{F}}_A &= T^{-1} \mathbf{Z}' \mathbf{J}_T \mathbf{Z} \\ &= \mathbf{\Lambda} (T^{-1} \mathbf{F}' \mathbf{J}_T \mathbf{F}) \mathbf{\Lambda}' + \mathbf{\Lambda} (T^{-1} \mathbf{F}' \mathbf{J}_T \boldsymbol{\omega}) + (T^{-1} \boldsymbol{\omega}' \mathbf{J}_T \mathbf{F}) \mathbf{\Lambda}' + T^{-1} \boldsymbol{\omega}' \mathbf{J}_T \boldsymbol{\omega} \\ &\quad + \mathbf{\Lambda} (T^{-1} \mathbf{F}' \mathbf{J}_T \boldsymbol{\varepsilon}) \zeta' + \zeta (T^{-1} \boldsymbol{\varepsilon}' \mathbf{J}_T \mathbf{F}) \mathbf{\Lambda} + \zeta (T^{-1} \boldsymbol{\varepsilon}' \mathbf{J}_T \boldsymbol{\omega}) \\ &\quad + (T^{-1} \boldsymbol{\omega}' \mathbf{J}_T \boldsymbol{\varepsilon}) \zeta' + \zeta (T^{-1} \boldsymbol{\varepsilon}' \mathbf{J}_T \boldsymbol{\varepsilon}) \zeta' \\ &= \mathbf{\Lambda} \mathbf{\Delta}_F \mathbf{\Lambda}' + \zeta (T^{-1} \boldsymbol{\varepsilon}' \mathbf{J}_T \boldsymbol{\varepsilon}) \zeta' + \mathbf{\Delta}_\omega + O_p(T^{-1/2}) \\ &= \mathbf{\Lambda}_f \mathbf{\Delta}_f \mathbf{\Lambda}'_f + \zeta (T^{-1} \boldsymbol{\varepsilon}' \mathbf{J}_T \boldsymbol{\varepsilon}) \zeta' + \mathbf{\Delta}_\omega + O_p(T^{-1/2}). \end{aligned}$$

The limit follows using Assumption 2.1, 5, Lemma 4 and 6 and noting that ζ has a finite

number of non-zero entries by Assumption 9.

$$\begin{aligned}
\hat{\mathbf{F}}_B &= N^{-\psi_f} T^{-2} \mathbf{Z}' \mathbf{J}_T \mathbf{X} \mathbf{J}_N \mathbf{X}' \mathbf{J}_T \mathbf{Z} \\
&= N^{-\psi_f} T^{-2} (\boldsymbol{\nu}_T \boldsymbol{\lambda}'_0 + \mathbf{F} \boldsymbol{\Lambda}' + \boldsymbol{\omega})' \mathbf{J}_T \mathbf{X} \mathbf{J}_N \mathbf{X}' \mathbf{J}_T (\boldsymbol{\nu}_T \boldsymbol{\lambda}'_0 + \mathbf{F} \boldsymbol{\Lambda}' + \boldsymbol{\omega}) \\
&\quad + N^{-\psi_f} T^{-2} \boldsymbol{\zeta} \boldsymbol{\varepsilon}' \mathbf{J}_T \mathbf{X} \mathbf{J}_N \mathbf{X}' \mathbf{J}_T (\boldsymbol{\nu}_T \boldsymbol{\lambda}'_0 + \mathbf{F} \boldsymbol{\Lambda}' + \boldsymbol{\omega} + \boldsymbol{\varepsilon} \boldsymbol{\zeta}') \\
&\quad + N^{-\psi_f} T^{-2} (\boldsymbol{\nu}_T \boldsymbol{\lambda}'_0 + \mathbf{F} \boldsymbol{\Lambda}' + \boldsymbol{\omega} + \boldsymbol{\varepsilon} \boldsymbol{\zeta}')' \mathbf{J}_T \mathbf{X} \mathbf{J}_N \mathbf{X}' \mathbf{J}_T \boldsymbol{\varepsilon} \boldsymbol{\zeta}' \\
&= \text{I} + \text{II} + \text{III}.
\end{aligned}$$

The probability limit of I was established in Lemma 4. Also note that II is transpose of III.

We establish the probability limit of III below.

$$\begin{aligned}
\text{III}' &= N^{-\psi_f} T^{-2} (\boldsymbol{\nu}_T \boldsymbol{\lambda}'_0 + \mathbf{F} \boldsymbol{\Lambda}' + \boldsymbol{\omega} + \boldsymbol{\varepsilon} \boldsymbol{\zeta}')' \mathbf{J}_T \mathbf{X} \mathbf{J}_N \mathbf{X}' \mathbf{J}_T \boldsymbol{\varepsilon} \boldsymbol{\zeta}' \\
&= \boldsymbol{\Lambda} (T^{-1} \mathbf{F}' \mathbf{J}_T \mathbf{F}) \left(N^{-\psi_f} \boldsymbol{\Phi}' \mathbf{J}_N \boldsymbol{\Phi} \right) (T^{-1} \mathbf{F}' \mathbf{J}_T \boldsymbol{\varepsilon}) \boldsymbol{\zeta}' + \boldsymbol{\Lambda} (T^{-1} \mathbf{F}' \mathbf{J}_T \mathbf{F}) \left(N^{-\psi_f} T^{-1} \boldsymbol{\Phi}' \mathbf{J}_N \boldsymbol{\varepsilon}' \mathbf{J}_T \boldsymbol{\varepsilon} \right) \boldsymbol{\zeta}' \\
&\quad + \boldsymbol{\Lambda} \left(N^{-\psi_f} T^{-1} \mathbf{F}' \mathbf{J}_T \boldsymbol{\varepsilon} \mathbf{J}_N \boldsymbol{\Phi} \right) (T^{-1} \mathbf{F}' \mathbf{J}_T \boldsymbol{\varepsilon}) \boldsymbol{\zeta}' + (T^{-1} \boldsymbol{\omega}' \mathbf{J}_T \mathbf{F}) \left(N^{-\psi_f} \boldsymbol{\Phi}' \mathbf{J}_N \boldsymbol{\Phi} \right) (T^{-1} \mathbf{F}' \mathbf{J}_T \boldsymbol{\varepsilon}) \boldsymbol{\zeta}' \\
&\quad + (T^{-1} \boldsymbol{\omega}' \mathbf{J}_T \mathbf{F}) \left(N^{-\psi_f} T^{-1} \boldsymbol{\Phi}' \mathbf{J}_N \boldsymbol{\varepsilon}' \mathbf{J}_T \boldsymbol{\varepsilon} \right) \boldsymbol{\zeta}' + \left(N^{-\psi_f} T^{-1} \boldsymbol{\omega}' \mathbf{J}_T \boldsymbol{\varepsilon} \mathbf{J}_N \boldsymbol{\Phi} \right) (T^{-1} \mathbf{F}' \mathbf{J}_T \boldsymbol{\varepsilon}) \boldsymbol{\zeta}' \\
&\quad + \boldsymbol{\zeta} (T^{-1} \boldsymbol{\varepsilon}' \mathbf{J}_T \mathbf{F}) \left(N^{-\psi_f} \boldsymbol{\Phi}' \mathbf{J}_N \boldsymbol{\Phi} \right) (T^{-1} \mathbf{F}' \mathbf{J}_T \boldsymbol{\varepsilon}) \boldsymbol{\zeta}' + \boldsymbol{\zeta} (T^{-1} \boldsymbol{\varepsilon}' \mathbf{J}_T \mathbf{F}) \left(N^{-\psi_f} T^{-1} \boldsymbol{\Phi}' \mathbf{J}_N \boldsymbol{\varepsilon}' \mathbf{J}_T \boldsymbol{\varepsilon} \right) \boldsymbol{\zeta}' \\
&\quad + \boldsymbol{\zeta} \left(N^{-\psi_f} T^{-1} \boldsymbol{\varepsilon}' \mathbf{J}_T \boldsymbol{\varepsilon} \mathbf{J}_N \boldsymbol{\Phi} \right) (T^{-1} \mathbf{F}' \mathbf{J}_T \boldsymbol{\varepsilon}) \boldsymbol{\zeta}' + \frac{N^{1-\psi_f}}{\sqrt{T}} \left(N^{-\psi_f} T^{-3/2} \boldsymbol{\omega}' \mathbf{J}_T \boldsymbol{\varepsilon} \mathbf{J}_N \boldsymbol{\varepsilon}' \mathbf{J}_T \boldsymbol{\varepsilon} \right) \boldsymbol{\zeta}' \\
&\quad + \frac{N^{1-\psi_f}}{\sqrt{T}} \boldsymbol{\Lambda} \left(N^{-\psi_f} T^{-3/2} \mathbf{F}' \mathbf{J}_T \boldsymbol{\varepsilon} \mathbf{J}_N \boldsymbol{\varepsilon}' \mathbf{J}_T \boldsymbol{\varepsilon} \right) \boldsymbol{\zeta}' + \frac{N^{1-\psi_f}}{\sqrt{T}} \boldsymbol{\zeta} \left(N^{-\psi_f} T^{-3/2} \boldsymbol{\varepsilon}' \mathbf{J}_T \boldsymbol{\varepsilon} \mathbf{J}_N \boldsymbol{\varepsilon}' \mathbf{J}_T \boldsymbol{\varepsilon} \right) \boldsymbol{\zeta}' \\
&= \mathbf{O}_p(\Xi_{NT}^{-1}).
\end{aligned}$$

The final equality comes from Lemma 2, 6, equation A2.1, Assumption 2.1, 4 and noting the fact that $\boldsymbol{\zeta}$ has finitely many non-zero entries given Assumption 9. Hence, $\hat{\mathbf{F}}_B = N^{-\psi_f} T^{-2} \mathbf{Z}' \mathbf{J}_T \mathbf{X} \mathbf{J}_N \mathbf{X}' \mathbf{J}_T \mathbf{Z} = \boldsymbol{\Lambda}_f \boldsymbol{\Delta}_f \mathcal{P}_f \boldsymbol{\Delta}_f \boldsymbol{\Lambda}'_f + \mathbf{O}_p(\Xi_{NT}^{-1})$.

$$\begin{aligned}
\hat{\mathbf{F}}_{C,t} &= N^{-\psi_f} T^{-1} \mathbf{Z}' \mathbf{J}_T \mathbf{X} \mathbf{J}_N \mathbf{x}_t \\
&= N^{-\psi_f} T^{-1} \mathbf{Z}' \mathbf{J}_T \mathbf{X} \mathbf{J}_N \phi_0 + N^{-\psi_f} T^{-1} (\boldsymbol{\nu}_T \boldsymbol{\lambda}'_0 + \mathbf{F} \boldsymbol{\Lambda}' + \boldsymbol{\omega})' \mathbf{J}_T \mathbf{X} \mathbf{J}_N \mathbf{x}_t + \boldsymbol{\zeta} (T^{-1} \boldsymbol{\varepsilon}' \mathbf{J}_T \mathbf{F}) \left(N^{-\psi_f} \boldsymbol{\Phi}' \mathbf{J}_N \boldsymbol{\Phi} \right) \\
&\quad + \boldsymbol{\zeta} (T^{-1} \boldsymbol{\varepsilon}' \mathbf{J}_T \mathbf{F}) \left(N^{-\psi_f} \boldsymbol{\Phi}' \mathbf{J}_N \boldsymbol{\varepsilon}_t \right) + \boldsymbol{\zeta} \left(N^{-\psi_f} T^{-1} \boldsymbol{\varepsilon}' \mathbf{J}_T \boldsymbol{\varepsilon} \mathbf{J}_N \boldsymbol{\Phi} \right) \mathbf{F}_t + \frac{N^{1-\psi_f}}{\sqrt{T}} \boldsymbol{\zeta} \left(N^{-1} T^{-1/2} \boldsymbol{\varepsilon}' \mathbf{J}_T \boldsymbol{\varepsilon} \mathbf{J}_N \boldsymbol{\varepsilon}_t \right) \\
&= N^{-\psi_f} T^{-1} \mathbf{Z}' \mathbf{J}_T \mathbf{X} \mathbf{J}_N \phi_0 + \boldsymbol{\Lambda}_f \boldsymbol{\Delta}_f \mathcal{P}_f \mathbf{f}_t + \mathbf{O}_p(\Xi_{NT}^{-1}).
\end{aligned}$$

The stochastic order of the second term was established in Lemma 4 which yields the order here since all terms except the first two are $O_p(\Xi_{NT}^{-1})$ given Lemma 6 and the fact that ζ has finitely many non-zero entries by Assumption 9.

Continuous mapping theorem yields the plm of $\hat{\mathbf{F}}_t$.

Lemma 8. *Under Assumptions 1-5, 8 and 9, if $\frac{N^{1-\psi_f}}{\sqrt{T}} = O(1)$ and $\frac{T}{N} = O(1)$,*

1. $\hat{\beta}_1 = T^{-1} \mathbf{Z}' \mathbf{J}_T \mathbf{Z} = \Lambda_f \Delta_f \Lambda_f' + \zeta (T^{-1} \varepsilon' \mathbf{J}_T \varepsilon) \zeta' + \Delta_\omega + O_p(T^{-1/2}).$
2. $\hat{\beta}_2 = N^{-\psi_f} T^{-2} \mathbf{Z}' \mathbf{J}_T \mathbf{X} \mathbf{J}_N \mathbf{X}' \mathbf{J}_T \mathbf{Z} = \Lambda_f \Delta_f \mathcal{P}_f \Delta_f \Lambda_f' + O_p(\Xi_{NT}^{-1}).$
3. $\hat{\beta}_3 = N^{-2\psi_f} T^{-3} \mathbf{Z}' \mathbf{J}_T \mathbf{X} \mathbf{J}_N \mathbf{X}' \mathbf{J}_T \mathbf{X} \mathbf{J}_N \mathbf{X}' \mathbf{J}_T \mathbf{Z} = \Lambda_f \Delta_f \mathcal{P}_f \Delta_f \mathcal{P}_f \Delta_f \Lambda_f' + O_p(\Xi_{NT}^{-1}).$
4. $\hat{\beta}_4 = N^{-\psi_f} T^{-2} \mathbf{Z}' \mathbf{J}_T \mathbf{X} \mathbf{J}_N \mathbf{X}' \mathbf{J}_T \mathbf{y} = \Lambda_f \Delta_f \mathcal{P}_f \Delta_f \beta_f + O_p(\Xi_{NT}^{-1}).$

Therefore,

$$\begin{aligned} \hat{\beta} &= (T^{-1} \mathbf{Z}' \mathbf{J}_T \mathbf{Z})^{-1} N^{-\psi_f} T^{-2} \mathbf{Z}' \mathbf{J}_T \mathbf{X} \mathbf{J}_N \mathbf{X}' \mathbf{J}_T \mathbf{Z} \\ &\quad \times \left(N^{-2\psi_f} T^{-3} \mathbf{Z}' \mathbf{J}_T \mathbf{X} \mathbf{J}_N \mathbf{X}' \mathbf{J}_T \mathbf{X} \mathbf{J}_N \mathbf{X}' \mathbf{J}_T \mathbf{Z} \right)^{-1} N^{-\psi_f} T^{-2} \mathbf{Z}' \mathbf{J}_T \mathbf{X} \mathbf{J}_N \mathbf{X}' \mathbf{J}_T \mathbf{y} \\ &= \hat{\beta}_1^{-1} \hat{\beta}_2 \hat{\beta}_3^{-1} \hat{\beta}_4 \end{aligned}$$

has the the probability limit under Assumption 6 given by,

$$\begin{aligned} \hat{\beta} &\xrightarrow[T, N \rightarrow \infty]{p} (\Lambda_f \Delta_f \Lambda_f' + \zeta (T^{-1} \varepsilon' \mathbf{J}_T \varepsilon) \zeta' + \Delta_\omega)^{-1} \Lambda_f \Delta_f \mathcal{P}_f \Delta_f \Lambda_f' (\Lambda_f \Delta_f \mathcal{P}_f \Delta_f \mathcal{P}_f \Delta_f \Lambda_f')^{-1} \\ &\quad \times \Lambda_f \Delta_f \mathcal{P}_f \Delta_f \beta_f. \end{aligned}$$

Proof:

$$\begin{aligned} \hat{\beta} &= (T^{-1} \mathbf{Z}' \mathbf{J}_T \mathbf{Z})^{-1} N^{-\psi_f} T^{-2} \mathbf{Z}' \mathbf{J}_T \mathbf{X} \mathbf{J}_N \mathbf{X}' \mathbf{J}_T \mathbf{Z} \\ &\quad \times \left(N^{-2\psi_f} T^{-3} \mathbf{Z}' \mathbf{J}_T \mathbf{X} \mathbf{J}_N \mathbf{X}' \mathbf{J}_T \mathbf{X} \mathbf{J}_N \mathbf{X}' \mathbf{J}_T \mathbf{Z} \right)^{-1} N^{-\psi_f} T^{-2} \mathbf{Z}' \mathbf{J}_T \mathbf{X} \mathbf{J}_N \mathbf{X}' \mathbf{J}_T \mathbf{y} \\ &= \hat{\beta}_1^{-1} \hat{\beta}_2 \hat{\beta}_3^{-1} \hat{\beta}_4. \end{aligned}$$

Note that $\hat{\beta}_1 = \hat{\mathbf{F}}_A$ and $\hat{\beta}_2 = \hat{\mathbf{F}}_B$ and their probability limits are established in Lemma 7.

The expressions for $\hat{\beta}_3$ and $\hat{\beta}_4$ are handled below. Note that,

$\hat{\beta}_3 = N^{-2\psi_f} T^{-3} \mathbf{Z}' \mathbf{J}_T \mathbf{X} \mathbf{J}_N \mathbf{X}' \mathbf{J}_T \mathbf{X} \mathbf{J}_N \mathbf{X}' \mathbf{J}_T \mathbf{Z}$ is essentially the product $\frac{\hat{\mathbf{F}}_C \mathbf{J}_T \hat{\mathbf{F}}_C'}{T}$ where $\hat{\mathbf{F}}_C$ is obtained by stacking $\hat{\mathbf{F}}_{C,t}$ horizontally. Using the probability limit of $\hat{\mathbf{F}}_{C,t}$ obtained in Lemma 7 standard arguments would imply that $plim \left(\frac{\hat{\mathbf{F}}_C \mathbf{J}_T \hat{\mathbf{F}}_C'}{T} \right) = \mathbf{\Lambda}_f \mathbf{\Delta}_f \mathcal{P}_f (T^{-1} \mathbf{f} \mathbf{J}_T \mathbf{f}) \mathcal{P}_f \mathbf{\Delta}_f \mathbf{\Lambda}_f'$ which is equal to $\mathbf{\Lambda}_f \mathbf{\Delta}_f \mathcal{P}_f \mathbf{\Delta}_f \mathcal{P}_f \mathbf{\Delta}_f \mathbf{\Lambda}_f'$ given Assumption 2.1. Using Lemma 6 and the expression for $\hat{\mathbf{F}}_{C,t}$ in Lemma 7 we can establish that $N^{-2\psi_f} T^{-3} \mathbf{Z}' \mathbf{J}_T \mathbf{X} \mathbf{J}_N \mathbf{X}' \mathbf{J}_T \mathbf{X} \mathbf{J}_N \mathbf{X}' \mathbf{J}_T \mathbf{Z} = \frac{\hat{\mathbf{F}}_C \mathbf{J}_T \hat{\mathbf{F}}_C'}{T} = \mathbf{\Lambda}_f \mathbf{\Delta}_f \mathcal{P}_f \mathbf{\Delta}_f \mathcal{P}_f \mathbf{\Delta}_f \mathbf{\Lambda}_f' + O_p(\Xi_{NT}^{-1})$.

$$\begin{aligned}
\hat{\beta}_4 &= N^{-\psi_f} T^{-2} \mathbf{Z}' \mathbf{J}_T \mathbf{X} \mathbf{J}_N \mathbf{X}' \mathbf{J}_T \mathbf{y} \\
&= N^{-\psi_f} T^{-2} (\iota_T \lambda'_0 + \mathbf{F} \mathbf{\Lambda}_f' + \boldsymbol{\omega})' \mathbf{J}_T \mathbf{X} \mathbf{J}_N \mathbf{X}' \mathbf{J}_T (\iota_T \beta_0 + \mathbf{F} \boldsymbol{\beta} + \boldsymbol{\eta}) \\
&\quad + N^{-\psi_f} T^{-2} \boldsymbol{\zeta} \boldsymbol{\varepsilon}' \mathbf{J}_T \mathbf{X} \mathbf{J}_N \mathbf{X}' \mathbf{J}_T (\iota_T \beta_0 + \mathbf{F} \boldsymbol{\beta} + \boldsymbol{\varepsilon} \boldsymbol{\gamma} + \boldsymbol{\eta}) + \\
&\quad N^{-\psi_f} T^{-2} (\iota_T \lambda'_0 + \mathbf{F} \mathbf{\Lambda}_f' + \boldsymbol{\omega} + \boldsymbol{\varepsilon} \boldsymbol{\gamma})' \mathbf{J}_T \mathbf{X} \mathbf{J}_N \mathbf{X}' \mathbf{J}_T \boldsymbol{\varepsilon} \boldsymbol{\gamma} \\
&= \text{I} + \text{II} + \text{III}.
\end{aligned}$$

The stochastic order of I was established in Lemma 5. III is $O_p(\Xi_{NT}^{-1})$, which can be seen simply by replacing $\boldsymbol{\zeta}'$ by $\boldsymbol{\gamma}$ in the III term of expression of $\hat{\mathbf{F}}_B$ in Lemma 7 and noting that $(\gamma_i = 0 \implies \zeta'_i = 0)$ by Assumption 9. We look at the transpose of II below.

$$\begin{aligned}
\text{II}' &= N^{-\psi_f} T^{-2} (\iota_T \beta_0 + \mathbf{F} \boldsymbol{\beta} + \boldsymbol{\varepsilon} \boldsymbol{\gamma} + \boldsymbol{\eta})' \mathbf{J}_T \mathbf{X} \mathbf{J}_N \mathbf{X}' \mathbf{J}_T \boldsymbol{\varepsilon} \boldsymbol{\zeta}' \\
&= \boldsymbol{\beta}' (T^{-1} \mathbf{F}' \mathbf{J}_T \mathbf{F}) \left(N^{-\psi_f} \boldsymbol{\Phi}' \mathbf{J}_N \boldsymbol{\Phi} \right) (T^{-1} \mathbf{F}' \mathbf{J}_T \boldsymbol{\varepsilon}) \boldsymbol{\zeta}' + \boldsymbol{\beta}' (T^{-1} \mathbf{F}' \mathbf{J}_T \mathbf{F}) \left(N^{-\psi_f} T^{-1} \boldsymbol{\Phi}' \mathbf{J}_N \boldsymbol{\varepsilon}' \mathbf{J}_T \boldsymbol{\varepsilon} \right) \boldsymbol{\zeta}' \\
&\quad + \boldsymbol{\beta}' \left(N^{-\psi_f} T^{-1} \mathbf{F}' \mathbf{J}_T \boldsymbol{\varepsilon} \mathbf{J}_N \boldsymbol{\Phi} \right) (T^{-1} \mathbf{F}' \mathbf{J}_T \boldsymbol{\varepsilon}) \boldsymbol{\zeta}' + (T^{-1} \boldsymbol{\eta}' \mathbf{J}_T \mathbf{F}) \left(N^{-\psi_f} \boldsymbol{\Phi}' \mathbf{J}_N \boldsymbol{\Phi} \right) (T^{-1} \mathbf{F}' \mathbf{J}_T \boldsymbol{\varepsilon}) \boldsymbol{\zeta}' \\
&\quad + (T^{-1} \boldsymbol{\eta}' \mathbf{J}_T \mathbf{F}) \left(N^{-\psi_f} T^{-1} \boldsymbol{\Phi}' \mathbf{J}_N \boldsymbol{\varepsilon}' \mathbf{J}_T \boldsymbol{\varepsilon} \right) \boldsymbol{\zeta}' + \left(N^{-\psi_f} T^{-1} \boldsymbol{\eta}' \mathbf{J}_T \boldsymbol{\varepsilon} \mathbf{J}_N \boldsymbol{\Phi} \right) (T^{-1} \mathbf{F}' \mathbf{J}_T \boldsymbol{\varepsilon}) \boldsymbol{\zeta}' \\
&\quad + \boldsymbol{\gamma}' (T^{-1} \boldsymbol{\varepsilon}' \mathbf{J}_T \mathbf{F}) \left(N^{-\psi_f} \boldsymbol{\Phi}' \mathbf{J}_N \boldsymbol{\Phi} \right) (T^{-1} \mathbf{F}' \mathbf{J}_T \boldsymbol{\varepsilon}) \boldsymbol{\zeta}' + \boldsymbol{\gamma}' (T^{-1} \boldsymbol{\varepsilon}' \mathbf{J}_T \mathbf{F}) \left(N^{-\psi_f} T^{-1} \boldsymbol{\Phi}' \mathbf{J}_N \boldsymbol{\varepsilon}' \mathbf{J}_T \boldsymbol{\varepsilon} \right) \boldsymbol{\zeta}' \\
&\quad + \boldsymbol{\gamma}' \left(N^{-\psi_f} T^{-1} \boldsymbol{\varepsilon}' \mathbf{J}_T \boldsymbol{\varepsilon} \mathbf{J}_N \boldsymbol{\Phi} \right) (T^{-1} \mathbf{F}' \mathbf{J}_T \boldsymbol{\varepsilon}) \boldsymbol{\zeta}' + \frac{N^{1-\psi_f}}{\sqrt{T}} \left(N^{-\psi_f} T^{-3/2} \boldsymbol{\eta}' \mathbf{J}_T \boldsymbol{\varepsilon} \mathbf{J}_N \boldsymbol{\varepsilon}' \mathbf{J}_T \boldsymbol{\varepsilon} \right) \boldsymbol{\zeta}' \\
&\quad + \frac{N^{1-\psi_f}}{\sqrt{T}} \boldsymbol{\beta}' \left(N^{-\psi_f} T^{-3/2} \mathbf{F}' \mathbf{J}_T \boldsymbol{\varepsilon} \mathbf{J}_N \boldsymbol{\varepsilon}' \mathbf{J}_T \boldsymbol{\varepsilon} \right) \boldsymbol{\zeta}' + \frac{N^{1-\psi_f}}{\sqrt{T}} \boldsymbol{\gamma}' \left(N^{-\psi_f} T^{-3/2} \boldsymbol{\varepsilon}' \mathbf{J}_T \boldsymbol{\varepsilon} \mathbf{J}_N \boldsymbol{\varepsilon}' \mathbf{J}_T \boldsymbol{\varepsilon} \right) \boldsymbol{\zeta}' \\
&= O_p(\Xi_{NT}^{-1}).
\end{aligned}$$

The final equality comes from Lemma 2, 6 and noting the fact that $\boldsymbol{\zeta}$ and $\boldsymbol{\gamma}$ have finitely

many non-zero entries given Assumption 9. Therefore, $\hat{\beta}_4 = \Lambda_f \Delta_f \mathcal{P}_f \Delta_f \beta + O_p(\Xi_{NT}^{-1})$.

Given the probability limits of $\hat{\beta}_1$, $\hat{\beta}_2$, $\hat{\beta}_3$ and $\hat{\beta}_4$, Continuous mapping theorem yields the probability limit in the statement of Lemma 8, i.e.,

$$\hat{\beta} \xrightarrow{p}_{T, N \rightarrow \infty} (\Lambda_f \Delta_f \Lambda_f' + \zeta (T^{-1} \epsilon' J_T \epsilon) \zeta' + \Delta_\omega)^{-1} \Lambda_f \Delta_f \mathcal{P}_f \Delta_f \Lambda_f' (\Lambda_f \Delta_f \mathcal{P}_f \Delta_f \mathcal{P}_f \Delta_f \Lambda_f')^{-1} \times \Lambda_f \Delta_f \mathcal{P}_f \Delta_f \beta.$$

Theorem 1(b) Let Assumptions 1-9 hold, $\frac{N^{1-\psi}}{\sqrt{T}} = O(1)$ and $\frac{T}{N} = O(1)$, then

$$\hat{y}_{t+h,f} - \mathbb{E}(y_{t+h} | \mathbf{F}_t) = O_p(\Xi_{NT}^{-1}).$$

Proof: From Lemma 4, 5, 7 and 8, we have established that

- $N^{-\psi_f} T^{-1} (\mathbf{x}_t - \bar{\mathbf{x}}) \mathbf{J}_N \mathbf{X}' \mathbf{J}_T \mathbf{Z} = \hat{\mathbf{F}}_{C,t} - \bar{\mathbf{F}}_C = (\mathbf{f}_t - \bar{\mathbf{f}})' \mathcal{P}_f \Delta_f \Lambda_f' + O_p(\Xi_{NT}^{-1}).$
- $N^{-2\psi_f} T^{-3} \mathbf{Z}' \mathbf{J}_T \mathbf{X} \mathbf{J}_N \mathbf{X}' \mathbf{J}_T \mathbf{X} \mathbf{J}_N \mathbf{X}' \mathbf{J}_T \mathbf{Z} = \Lambda_f \Delta_f \mathcal{P}_f \Delta_f \mathcal{P}_f \Delta_f \Lambda_f' + O_p(\Xi_{NT}^{-1}).$
- $N^{-\psi} T^{-2} \mathbf{Z}' \mathbf{J}_T \mathbf{X} \mathbf{J}_N \mathbf{X}' \mathbf{J}_T \mathbf{y} = \Lambda_f \Delta_f \mathcal{P}_f \Delta_f \beta_f + O_p(\Xi_{NT}^{-1}).$

Given these results and the fact that for all i , $T^{-1/2} \sum_t \varepsilon_{it} = O_p(1)$ by Lemma 1.3, we get that $\hat{y}_{t+h,f} = \beta_0 + \mathbf{F}_t' \beta + O_p(\Xi_{NT}^{-1})$ using the same steps as in the proof of Theorem 1(a).

The Proofs for Theorem3(b) and Theorem4(b) respectively, follow similarly given the rates derived in Lemmas 7 and 8.

A4 Proof of Theorem 5

We now proceed to prove Theorem 5 which deals with stage 2 of 3PRF-Lasso. We introduce 2 Lemmas which shall be used in the subsequent proof of Theorem 5

Lemma 9. Define $\hat{x}_{it} \equiv \hat{\phi}_{0,i} + \hat{\mathbf{F}}_t' \hat{\phi}_i$, where $\hat{\phi}_{0,i}$ and $\hat{\phi}_i$ are obtained from stage-2 Pass 1 regression. Let Assumptions 1-6 and 8 hold, $\frac{N^{1-\psi_f}}{\sqrt{T}} = O(1)$ and $\frac{T}{N} = O(1)$, then

$$\hat{\varepsilon}_{it} - (\varepsilon_{it} + \mathbf{g}_t' \phi_{ig} - \bar{\mathbf{g}}' \phi_{ig}) = O_p(\Xi_{NT}^{-1}).$$

.

Proof: The proof proceeds in a similar manner to Theorem1(b). The target \mathbf{y} can be replaced by \mathbf{x}_i and the proof follows similar steps.

First notice that, using the same steps as in proof of Lemma 4 for $\hat{\mathbf{F}}_B$, we can get

$$N^{-\psi_f} T^{-2} \mathbf{W}'_{XZ} \mathbf{S}_{X\mathbf{x}_i} = \mathbf{\Lambda} (T^{-1} \mathbf{F}' \mathbf{J}_T \mathbf{F}) \left(N^{-\psi_f} \mathbf{\Phi}' \mathbf{J}_N \mathbf{\Phi} \right) (T^{-1} \mathbf{F}' \mathbf{J}_T \mathbf{F}) \phi_i + O_p(\Xi_{NT}^{-1}).$$

Employing the fact that $\mathbf{\Lambda} = \begin{bmatrix} \mathbf{\Lambda}_f & \mathbf{0} \end{bmatrix}$ (Assumption 5), we have

$$\begin{aligned} & \mathbf{\Lambda} (T^{-1} \mathbf{F}' \mathbf{J}_T \mathbf{F}) \left(N^{-\psi_f} \mathbf{\Phi}' \mathbf{J}_N \mathbf{\Phi} \right) (T^{-1} \mathbf{F}' \mathbf{J}_T \mathbf{F}) \phi_i \\ &= \mathbf{\Lambda}_f (T^{-1} \mathbf{f}' \mathbf{J}_T \mathbf{f}) \left(N^{-\psi_f} \mathbf{\Phi}'_f \mathbf{J}_N \mathbf{\Phi}_f \right) (T^{-1} \mathbf{f}' \mathbf{J}_T \mathbf{f}) \phi_{if} \\ &+ \mathbf{\Lambda}_f (T^{-1} \mathbf{f}' \mathbf{J}_T \mathbf{f}) \left(N^{-\psi_f} \mathbf{\Phi}'_f \mathbf{J}_N \mathbf{\Phi}_g \right) (T^{-1} \mathbf{g}' \mathbf{J}_T \mathbf{f}) \phi_{if} \\ &+ \mathbf{\Lambda}_f (T^{-1} \mathbf{f}' \mathbf{J}_T \mathbf{g}) \left(N^{-\psi_f} \mathbf{\Phi}'_g \mathbf{J}_N \mathbf{\Phi}_f \right) (T^{-1} \mathbf{f}' \mathbf{J}_T \mathbf{f}) \phi_{if} \\ &+ \frac{N^{\psi_g - \psi_f}}{T} \mathbf{\Lambda}_f \left(T^{-1/2} \mathbf{f}' \mathbf{J}_T \mathbf{g} \right) \left(N^{-\psi_g} \mathbf{\Phi}'_g \mathbf{J}_N \mathbf{\Phi}_g \right) \left(T^{-1/2} \mathbf{g}' \mathbf{J}_T \mathbf{f} \right) \phi_{if} \\ &+ \mathbf{\Lambda}_f (T^{-1} \mathbf{f}' \mathbf{J}_T \mathbf{f}) \left(N^{-\psi_f} \mathbf{\Phi}'_f \mathbf{J}_N \mathbf{\Phi}_f \right) (T^{-1} \mathbf{f}' \mathbf{J}_T \mathbf{g}) \phi_{ig} \\ &+ \mathbf{\Lambda}_f (T^{-1} \mathbf{f}' \mathbf{J}_T \mathbf{f}) \left(N^{-\psi_f} \mathbf{\Phi}'_f \mathbf{J}_N \mathbf{\Phi}_g \right) (T^{-1} \mathbf{g}' \mathbf{J}_T \mathbf{g}) \phi_{ig} \\ &+ \mathbf{\Lambda}_f (T^{-1} \mathbf{f}' \mathbf{J}_T \mathbf{g}) \left(N^{-\psi_f} \mathbf{\Phi}'_g \mathbf{J}_N \mathbf{\Phi}_f \right) (T^{-1} \mathbf{f}' \mathbf{J}_T \mathbf{g}) \phi_{ig} \\ &+ \frac{N^{\psi_g - \psi_f}}{\sqrt{T}} \mathbf{\Lambda}_f \left(T^{-1/2} \mathbf{f}' \mathbf{J}_T \mathbf{g} \right) \left(N^{-\psi_g} \mathbf{\Phi}'_g \mathbf{J}_N \mathbf{\Phi}_g \right) (T^{-1} \mathbf{g}' \mathbf{J}_T \mathbf{g}) \phi_{ig} \\ &= \mathbf{\Lambda}_f \mathbf{\Delta}_f \mathcal{P}_f \mathbf{\Delta}_f \phi_{if} + O_p(\Xi_{NT}^{-1}) + O_p(\Xi_{NT}^{-1}) \phi_{ig} \\ &= \mathbf{\Lambda}_f \mathbf{\Delta}_f \mathcal{P}_f \mathbf{\Delta}_f \phi_{if} + O_p(\Xi_{NT}^{-1}). \end{aligned}$$

The result follows from Assumption 2.1 and 4. Substituting this in the expression of \hat{x}_{it} we get,

$$\begin{aligned}
\hat{x}_{it} &= \bar{\mathbf{x}}_i + \left(N^{-\psi_f} T^{-1} (\mathbf{x}_t - \bar{\mathbf{x}}) \mathbf{W}_{XZ} \right) \left(N^{-2\psi_f} T^{-3} \mathbf{W}'_{XZ} \mathbf{S}_{XX} \mathbf{W}_{XZ} \right)^{-1} \left(N^{-\psi_f} T^{-2} \mathbf{W}'_{XZ} \mathbf{S}_{X\mathbf{x}_i} \right) \\
&= \phi_{0,i} + \bar{\mathbf{F}}' \boldsymbol{\phi}_i + O_p(T^{-1/2}) + \left((\mathbf{f}_t - \bar{\mathbf{f}})' \mathcal{P}_f \boldsymbol{\Delta}_f \boldsymbol{\Lambda}'_f + O_p(\Xi_{NT}^{-1}) \right) \\
&\quad \times [\boldsymbol{\Lambda}_f \boldsymbol{\Delta}_f \mathcal{P}_f \boldsymbol{\Delta}_f \mathcal{P}_f \boldsymbol{\Delta}_f \boldsymbol{\Lambda}'_f + O_p(\Xi_{NT}^{-1})]^{-1} (\boldsymbol{\Lambda}_f \boldsymbol{\Delta}_f \mathcal{P}_f \boldsymbol{\Delta}_f \boldsymbol{\phi}_{if} + O_p(\Xi_{NT}^{-1}) \boldsymbol{\phi}_{ig} + O_p(\Xi_{NT}^{-1})) \\
&= \phi_{0,i} + \bar{\mathbf{f}}' \boldsymbol{\phi}_{if} + \bar{\mathbf{g}}' \boldsymbol{\phi}_{ig} + O_p(T^{-1/2}) + (\mathbf{f}_t - \bar{\mathbf{f}})' \mathcal{P}_1 \boldsymbol{\Delta}_{f,1} \boldsymbol{\Lambda}'_f \\
&\quad \times [\boldsymbol{\Lambda}_f \boldsymbol{\Delta}_{f,1} \mathcal{P}_1 \boldsymbol{\Delta}_{f,1} \mathcal{P}_1 \boldsymbol{\Delta}_{f,1} \boldsymbol{\Lambda}_f]^{-1} \boldsymbol{\Lambda}_f \boldsymbol{\Delta}_{f,1} \mathcal{P}_1 \boldsymbol{\Delta}_{f,1} \boldsymbol{\phi}_{if} + O_p(\Xi_{NT}^{-1}) + O_p(\Xi_{NT}^{-1}) \boldsymbol{\phi}_{ig} \\
&= \phi_{0,i} + \bar{\mathbf{g}}' \boldsymbol{\phi}_{ig} + O_p(T^{-1/2}) + \mathbf{f}'_t \mathcal{P}_1 \boldsymbol{\Delta}_{f,1} \boldsymbol{\Lambda}'_f \\
&\quad \times [\boldsymbol{\Lambda}_f \boldsymbol{\Delta}_{f,1} \mathcal{P}_1 \boldsymbol{\Delta}_{f,1} \mathcal{P}_1 \boldsymbol{\Delta}_{f,1} \boldsymbol{\Lambda}_f]^{-1} \boldsymbol{\Lambda}_f \boldsymbol{\Delta}_{f,1} \mathcal{P}_1 \boldsymbol{\Delta}_{f,1} \boldsymbol{\phi}_{if} + O_p(\Xi_{NT}^{-1}) + O_p(\Xi_{NT}^{-1}) \boldsymbol{\phi}_{ig} \\
&= \phi_{0,i} + \bar{\mathbf{g}}' \boldsymbol{\phi}_{ig} + \mathbf{f}'_t \boldsymbol{\phi}_{if} + O_p(\Xi_{NT}^{-1}) + O_p(\Xi_{NT}^{-1}) \boldsymbol{\phi}_{ig} \\
\therefore \hat{\varepsilon}_{it} &= x_{it} - \hat{x}_{it} = (\phi_{0,i} + \mathbf{g}'_t \boldsymbol{\phi}_{ig} + \mathbf{f}'_t \boldsymbol{\phi}_{if} + \varepsilon_{it}) - (\phi_{0,i} + \bar{\mathbf{g}}' \boldsymbol{\phi}_{ig} + \mathbf{f}'_t \boldsymbol{\phi}_{if} + O_p(\Xi_{NT}^{-1}) + O_p(\Xi_{NT}^{-1}) \boldsymbol{\phi}_{ig}) \\
&\implies \hat{\varepsilon}_{it} - (\varepsilon_{it} + \mathbf{g}'_t \boldsymbol{\phi}_{ig} - \bar{\mathbf{g}}' \boldsymbol{\phi}_{ig}) = O_p(\Xi_{NT}^{-1}) + O_p(\Xi_{NT}^{-1}) \boldsymbol{\phi}_{ig} \\
&\implies \hat{\varepsilon}_{it} - (\varepsilon_{it} + \mathbf{g}'_t \boldsymbol{\phi}_{ig} - \bar{\mathbf{g}}' \boldsymbol{\phi}_{ig}) = O_p(\Xi_{NT}^{-1}).
\end{aligned}$$

The stochastic orders for the matrices $N^{-\psi_f} T^{-1} (\mathbf{x}_t - \bar{\mathbf{x}}) \mathbf{W}_{XZ}$ and $N^{-2\psi_f} T^{-3} \mathbf{W}'_{XZ} \mathbf{S}_{XX} \mathbf{W}_{XZ}$ were obtained in Lemma 7 and 8 respectively. Noting that $\frac{\sum_{s=1}^T \varepsilon_{is}}{T} = O_p(T^{-1/2})$ by Lemma 1.3, we obtain the second equality.

Lemma 10. Define $\tilde{\boldsymbol{\eta}} \equiv \hat{\mathbf{u}} - \hat{\varepsilon} \boldsymbol{\gamma}$, where $\hat{\mathbf{u}} = \mathbf{y} - \hat{\mathbf{y}}_f = \mathbf{y} - \nu_T \bar{\mathbf{y}} - \mathbf{J}_T \hat{\mathbf{F}} \hat{\boldsymbol{\beta}}$.

$$\max_i \left(\frac{\Xi_{NT}}{T} \right) \hat{\varepsilon}'_i \tilde{\boldsymbol{\eta}} = \max_i \left(\frac{\Xi_{NT}}{T} \right) \varepsilon'_i \boldsymbol{\eta} + O_p(1).$$

Proof: Adding and subtracting terms,

$$\begin{aligned}
\max_i \left(\frac{\Xi_{NT}}{T} \right) \hat{\varepsilon}'_i \tilde{\boldsymbol{\eta}} &= \left(\frac{\Xi_{NT}}{T} \right) \max_i (\varepsilon_i + \mathbf{J}_T \mathbf{g} \boldsymbol{\phi}_{ig})' \boldsymbol{\eta} + \left(\frac{\Xi_{NT}}{T} \right) \max_i (\varepsilon_i + \mathbf{J}_T \mathbf{g} \boldsymbol{\phi}_{ig})' (\tilde{\boldsymbol{\eta}} - \boldsymbol{\eta}) \\
&\quad + \left(\frac{\Xi_{NT}}{T} \right) \max_i (\hat{\varepsilon}_i - (\varepsilon_i + \mathbf{J}_T \mathbf{g} \boldsymbol{\phi}_{ig}))' \boldsymbol{\eta} + \left(\frac{\Xi_{NT}}{T} \right) \max_i (\hat{\varepsilon}_i - (\varepsilon_i + \mathbf{J}_T \mathbf{g} \boldsymbol{\phi}_{ig}))' (\tilde{\boldsymbol{\eta}} - \boldsymbol{\eta}) \\
&= \text{I} + \text{II} + \text{III} + \text{IV}.
\end{aligned}$$

We show that $\text{I} = \max_i \left(\frac{\Xi_{NT}}{T} \right) \varepsilon'_i \boldsymbol{\eta} + O_p(1)$ and II, III and IV are $O_p(1)$.

Item I:

$$\begin{aligned} \max_i \left(\frac{\Xi_{NT}}{T} \right) (\boldsymbol{\varepsilon}_i + \mathbf{J}_T \mathbf{g} \phi_{ig})' \boldsymbol{\eta} &= \left(\frac{\Xi_{NT}}{T} \right) \max_i \boldsymbol{\varepsilon}_i' \boldsymbol{\eta} + \left(\frac{\Xi_{NT}}{T} \right) \left(\max_i \phi_{ig} \right) \mathbf{g}' \mathbf{J}_T \boldsymbol{\eta} \\ &= \max_i \left(\frac{\Xi_{NT}}{T} \right) \boldsymbol{\varepsilon}_i' \boldsymbol{\eta} + O_p(1). \end{aligned} \quad (\text{A4.1})$$

Where the final line follows from the fact that $\frac{\Xi_{NT}}{T} \leq \frac{1}{\sqrt{T}}$, $\max_i \phi_{ig}$ is $O_p(1)$ by Assumption 7.1 and $\frac{\mathbf{g}' \mathbf{J}_T \boldsymbol{\eta}}{T^{1/2}}$ is $O_p(1)$ by Lemma 2.2.

Item II : Note that $\boldsymbol{\eta} - \tilde{\boldsymbol{\eta}} = (\mathbf{y} - \mathbf{y}_f - \boldsymbol{\varepsilon} \boldsymbol{\gamma}) - (\mathbf{y} - \hat{\mathbf{y}}_f - \hat{\boldsymbol{\varepsilon}} \boldsymbol{\gamma}) = (\hat{\mathbf{y}}_f - \mathbf{y}_f) + (\hat{\boldsymbol{\varepsilon}} - \boldsymbol{\varepsilon}) \boldsymbol{\gamma}$. Therefore,

$$\begin{aligned} \left(\frac{\Xi_{NT}}{T} \right) (\boldsymbol{\varepsilon}_i + \mathbf{J}_T \mathbf{g} \phi_{ig})' (\tilde{\boldsymbol{\eta}} - \boldsymbol{\eta}) &= \left(\frac{\Xi_{NT}}{T} \right) (\tilde{\boldsymbol{\eta}} - \boldsymbol{\eta})' (\boldsymbol{\varepsilon}_i + \mathbf{J}_T \mathbf{g} \phi_{ig}) \\ &= \left(\frac{\Xi_{NT}}{T} \right) (\hat{\mathbf{y}}_f - \mathbf{y}_f)' \boldsymbol{\varepsilon}_i + \left(\frac{\Xi_{NT}}{T} \right) (\hat{\mathbf{y}}_f - \mathbf{y}_f)' \mathbf{J}_T \mathbf{g} \phi_{ig} \\ &\quad + \left(\frac{\Xi_{NT}}{T} \right) \boldsymbol{\gamma}' (\hat{\boldsymbol{\varepsilon}} - \boldsymbol{\varepsilon})' \boldsymbol{\varepsilon}_i + \left(\frac{\Xi_{NT}}{T} \right) \boldsymbol{\gamma}' (\hat{\boldsymbol{\varepsilon}} - \boldsymbol{\varepsilon})' \mathbf{J}_T \mathbf{g} \phi_{ig} \\ &= \mathcal{A}_i + \mathcal{B}_i + \mathcal{C}_i + \mathcal{D}_i. \end{aligned}$$

Notice that terms $\mathcal{A}_i, \mathcal{B}_i, \mathcal{C}_i$ and \mathcal{D}_i are all scalars. Therefore $\mathcal{A}_i = \|\mathcal{A}_i\|_1 = \|\mathcal{A}_i\|_\infty$. Same holds for $\mathcal{B}_i, \mathcal{C}_i$ and \mathcal{D}_i . We use this fact throughout the proof. We look at all these terms separately. From Lemma 2 and the expression for \mathbf{y} in the proof of Theorem 1(a) and Theorem 1(b), we have that $(\hat{\mathbf{y}}_f - \mathbf{y}_f)' = O_p(\Xi_{NT}^{-1}) \mathbf{F}' \mathbf{J}_T + O_p(1) (\hat{\mathbf{F}}_C - \boldsymbol{\Lambda}_f \boldsymbol{\Delta}_f \mathcal{P}_f \mathbf{f}') \mathbf{J}_T + \boldsymbol{\gamma}'_s (\boldsymbol{\nu}_T \bar{\boldsymbol{\varepsilon}}_s)' + (\boldsymbol{\nu}_T \bar{\boldsymbol{\eta}})'$. Therefore,

$$\begin{aligned} \mathcal{A}_i &= \left(\frac{\Xi_{NT}}{T} \right) (\hat{\mathbf{y}}_f - \mathbf{y}_f)' \boldsymbol{\varepsilon}_i \\ &= \Xi_{NT} O_p(\Xi_{NT}^{-1}) (T^{-1} \mathbf{F}' \mathbf{J}_T \boldsymbol{\varepsilon}_i) \\ &\quad + O_p(1) \left(\frac{\Xi_{NT}}{T} \right) (\hat{\mathbf{F}}_C - \boldsymbol{\Lambda}_f \boldsymbol{\Delta}_f \mathcal{P}_f \mathbf{f}') \mathbf{J}_T \boldsymbol{\varepsilon}_i + \left(\frac{\Xi_{NT}}{T} \right) \boldsymbol{\gamma}'_s (\boldsymbol{\nu}_T \bar{\boldsymbol{\varepsilon}}_s)' \boldsymbol{\varepsilon}_i + \left(\frac{\Xi_{NT}}{T} \right) (\boldsymbol{\nu}_T \bar{\boldsymbol{\eta}})' \boldsymbol{\varepsilon}_i \\ &= \mathcal{A}_{1i} + \mathcal{A}_{2i} + \mathcal{A}_{3i} + \mathcal{A}_{4i}. \end{aligned}$$

The first term \mathcal{A}_{1i} can be expanded as,

$$\begin{aligned}\mathcal{A}_{1i} &= \Xi_{NT} \mathbf{O}_p(\Xi_{NT}^{-1}) (T^{-1} \mathbf{F}' \mathbf{J}_T \boldsymbol{\varepsilon}_i) \\ &= \mathbf{O}_p(1) (T^{-1} \mathbf{F}' \mathbf{J}_T \boldsymbol{\varepsilon}_i) \\ &= \mathbf{O}_p(1) (T^{-1} \mathbf{F}' \boldsymbol{\varepsilon}_i) - \mathbf{O}_p(1) (T^{-1} \mathbf{F}' \boldsymbol{\nu}_T \bar{\boldsymbol{\varepsilon}}_i) .\end{aligned}$$

Therefore, by Triangle inequality,

$$\|\mathcal{A}_{1i}\|_\infty \leq \|\mathbf{O}_p(1)\|_\infty \left\| \frac{1}{T} \mathbf{F}' \boldsymbol{\varepsilon}_i \right\|_\infty + \left\| \frac{1}{T} \mathbf{O}_p(1) \mathbf{F}' \right\|_\infty \|\boldsymbol{\nu}_T \bar{\boldsymbol{\varepsilon}}_i\|_\infty .$$

Since the $\mathbf{O}_p(1)$ matrix listed above is a finite dimensional matrix, it's L_∞ norm will have the same order as it's elements. Also, $\mathbf{O}_p(1) \mathbf{F}'$ is a $L \times T$, ($L < \infty$) matrix with all elements having bounded second moments given Assumptions 2 and 3. Hence, its L_∞ norm will scale with at most T and therefore $\left\| \frac{1}{T} \mathbf{O}_p(1) \mathbf{F}' \right\|_\infty$ has a maximum order $O_p(1)$. $\boldsymbol{\nu}_T \bar{\boldsymbol{\varepsilon}}_i$ has all same elements, hence its L_∞ norm is equal to any element in this vector. Hence, we have, Therefore

$$\begin{aligned}\max_i \|\mathcal{A}_{1i}\|_\infty &\leq \|\mathbf{O}_p(1)\|_\infty \max_i \left\| \frac{1}{T} \mathbf{F}' \boldsymbol{\varepsilon}_i \right\|_\infty + \left\| \frac{1}{T} \mathbf{O}_p(1) \mathbf{F}' \right\|_\infty \max_i |\boldsymbol{\nu}_T \bar{\boldsymbol{\varepsilon}}_i| \\ &= \mathbf{O}_p \left(\frac{(\log N)^{r_3}}{\sqrt{T}} \right) + \mathbf{O}_p \left(\frac{(\log N)^{r_2}}{\sqrt{T}} \right) .\end{aligned}$$

The final line follows from Assumptions 7.3 and 7.4. Hence by Assumption 10, $\max_i \mathcal{A}_{1i}$ is $O_p(1)$.

We can expand \mathcal{A}_{2i} using Lemma 4 as

$$\begin{aligned}
\mathcal{A}_{2i} &= \mathbf{O}_p(1) \left(\frac{\Xi_{NT}}{T} \right) \left(\hat{\mathbf{F}}_C - \mathbf{\Lambda}_f \mathbf{\Delta}_f \mathcal{P}_f \mathbf{f}' \right) \mathbf{J}_T \boldsymbol{\varepsilon}_i \\
&= \mathbf{O}_p(1) \Xi_{NT} \left\{ \mathbf{\Lambda} \left(N^{-\psi_f} T^{-1} \mathbf{F}' \mathbf{J}_T \boldsymbol{\varepsilon} \mathbf{J}_N \mathbf{\Phi} \right) (T^{-1} \mathbf{F}' \mathbf{J}_T \boldsymbol{\varepsilon}_i) \right. \\
&\quad + (T^{-1} \boldsymbol{\omega}' \mathbf{J}_T \mathbf{F}) \left(N^{-\psi_f} \mathbf{\Phi}' \mathbf{J}_N \mathbf{\Phi} \right) (T^{-1} \mathbf{F}' \mathbf{J}_T \boldsymbol{\varepsilon}_i) + \left(N^{-\psi_f} T^{-1} \boldsymbol{\omega}' \mathbf{J}_T \boldsymbol{\varepsilon} \mathbf{J}_N \mathbf{\Phi} \right) (T^{-1} \mathbf{F}' \mathbf{J}_T \boldsymbol{\varepsilon}_i) \\
&\quad + \zeta (T^{-1} \boldsymbol{\varepsilon}' \mathbf{J}_T \mathbf{F}) \left(N^{-\psi_f} \mathbf{\Phi}' \mathbf{J}_N \mathbf{\Phi} \right) (T^{-1} \mathbf{F}' \mathbf{J}_T \boldsymbol{\varepsilon}_i) + \zeta \left(N^{-\psi_f} T^{-1} \boldsymbol{\varepsilon}' \mathbf{J}_T \boldsymbol{\varepsilon} \mathbf{J}_N \mathbf{\Phi} \right) (T^{-1} \mathbf{F}' \mathbf{J}_T \boldsymbol{\varepsilon}_i) \\
&\quad + \mathbf{\Lambda} (T^{-1} \mathbf{F}' \mathbf{J}_T \mathbf{F}) \left(N^{-\psi_f} T^{-1} \mathbf{\Phi}' \mathbf{J}_N \boldsymbol{\varepsilon}' \mathbf{J}_T \boldsymbol{\varepsilon}_i \right) + (T^{-1} \boldsymbol{\omega}' \mathbf{J}_T \mathbf{F}) \left(N^{-\psi_f} T^{-1} \mathbf{\Phi}' \mathbf{J}_N \boldsymbol{\varepsilon}' \mathbf{J}_T \boldsymbol{\varepsilon}_i \right) \\
&\quad + \frac{N^{1-\psi_f}}{\delta_{NT} \sqrt{T}} \mathbf{\Lambda} \left(\delta_{NT} N^{-1} T^{-3/2} \mathbf{F}' \mathbf{J}_T \boldsymbol{\varepsilon} \mathbf{J}_N \boldsymbol{\varepsilon} \mathbf{J}_T \boldsymbol{\varepsilon}_i \right) + \frac{N^{1-\psi_f}}{\delta_{NT} \sqrt{T}} \left(\delta_{NT} N^{-1} T^{-3/2} \boldsymbol{\omega}' \mathbf{J}_T \boldsymbol{\varepsilon} \mathbf{J}_N \boldsymbol{\varepsilon} \mathbf{J}_T \boldsymbol{\varepsilon}_i \right) \\
&\quad + \frac{N^{1-\psi_f}}{\delta_{NT} \sqrt{T}} \zeta \left(\delta_{NT} N^{-1} T^{-3/2} \boldsymbol{\varepsilon}' \mathbf{J}_T \boldsymbol{\varepsilon} \mathbf{J}_N \boldsymbol{\varepsilon} \mathbf{J}_T \boldsymbol{\varepsilon}_i \right) + \zeta (T^{-1} \boldsymbol{\varepsilon}' \mathbf{J}_T \mathbf{F}) \left(N^{-\psi_f} T^{-1} \mathbf{\Phi}' \mathbf{J}_N \boldsymbol{\varepsilon}' \mathbf{J}_T \boldsymbol{\varepsilon}_i \right) \\
&\quad + \mathbf{\Lambda}_f (T^{-1} \mathbf{f}' \mathbf{J}_T \mathbf{f}) \left(N^{-\psi_f} \mathbf{\Phi}'_f \mathbf{J}_N \mathbf{\Phi}_g \right) (T^{-1} \mathbf{g}' \mathbf{J}_T \boldsymbol{\varepsilon}_i) + \mathbf{\Lambda}_f (T^{-1} \mathbf{f}' \mathbf{J}_T \mathbf{g}) \left(N^{-\psi_f} \mathbf{\Phi}'_g \mathbf{J}_N \mathbf{\Phi}_f \right) (T^{-1} \mathbf{f}' \mathbf{J}_T \boldsymbol{\varepsilon}_i) \\
&\quad \left. + \frac{N^{\psi_g - \psi_f}}{\sqrt{T}} \mathbf{\Lambda}_f \left(T^{-1/2} \mathbf{f}' \mathbf{J}_T \mathbf{g} \right) \left(N^{-\psi_g} \mathbf{\Phi}'_g \mathbf{J}_N \mathbf{\Phi}_g \right) (T^{-1} \mathbf{g}' \mathbf{J}_T \boldsymbol{\varepsilon}_i) \right\}.
\end{aligned}$$

Given that ζ has finitely many non-zero entries by Assumption 9, $\|\zeta\|_\infty$ and $\|\zeta\|_1$ are both $\mathbf{O}_p(1)$. Also, given the orders derived in 2 and 6, and the fact that $\Xi_{NT} < \delta_{NT}$, we can say that \mathcal{A}_{2i} is a sum of 3 type of terms.

1. $\mathcal{A}_{2i.1}$: $\mathbf{O}_p(1) (T^{-1} \mathbf{F}' \mathbf{J}_T \boldsymbol{\varepsilon}_i)$ where the $\mathbf{O}_p(1)$ term is a finite dimensional matrix.
2. $\mathcal{A}_{2i.2}$: $\frac{N^{1-\psi_f}}{\sqrt{T}} \frac{\mathbf{D} \boldsymbol{\varepsilon}_i}{T}$ where \mathbf{D} is a $L \times T$ $\mathbf{O}_p(1)$ matrix, invariant across t and i , with all terms having bounded second moments.
3. $\mathcal{A}_{2i.3}$: $\Xi_{NT} \mathbf{O}_p(1) (N^{-\psi_f} T^{-1} \mathbf{\Phi}'_f \mathbf{J}_N \boldsymbol{\varepsilon}' \mathbf{J}_T \boldsymbol{\varepsilon}_i) + \Xi_{NT} \mathbf{O}_p(T^{-1/2}) (N^{-\psi_f} T^{-1} \mathbf{\Phi}'_g \mathbf{J}_N \boldsymbol{\varepsilon}' \mathbf{J}_T \boldsymbol{\varepsilon}_i)$, where the $\mathbf{O}_p(1)$ and $\mathbf{O}_p(T^{-1/2})$ terms are finite dimensional matrices invariant across t and i .[§]

For $\mathcal{A}_{2i.1}$, we follow the same proof as in \mathcal{A}_{1i} to show that its maximum value over i is bounded under Assumption 10.

[§]This follows from the observation that $\mathbf{\Lambda} (T^{-1} \mathbf{F}' \mathbf{J}_T \mathbf{F}) (N^{-\psi_f} T^{-1} \mathbf{\Phi}' \mathbf{J}_N \boldsymbol{\varepsilon}' \mathbf{J}_T \boldsymbol{\varepsilon}_i) = \mathbf{\Lambda}_f (T^{-1} \mathbf{f}' \mathbf{J}_T \mathbf{f}) (N^{-\psi_f} T^{-1} \mathbf{\Phi}'_f \mathbf{J}_N \boldsymbol{\varepsilon}' \mathbf{J}_T \boldsymbol{\varepsilon}_i) + T^{-1/2} \mathbf{\Lambda}_f (T^{-1/2} \mathbf{f}' \mathbf{J}_T \mathbf{g}) (N^{-\psi_f} \mathbf{\Phi}'_g \mathbf{J}_N \boldsymbol{\varepsilon}' \mathbf{J}_T \boldsymbol{\varepsilon}_i)$ and noticing that the rest of the terms pre-multiplying $(N^{-\psi_f} T^{-1} \mathbf{\Phi}' \mathbf{J}_N \boldsymbol{\varepsilon}' \mathbf{J}_T \boldsymbol{\varepsilon}_i)$ are $\mathbf{O}_p(T^{-1/2})$.

For $\mathcal{A}_{2i.2}$, we have,

$$\begin{aligned} \left\| \frac{N^{1-\psi_f}}{\sqrt{T}} \frac{\mathbf{D}\boldsymbol{\varepsilon}_i}{T} \right\|_{\infty} &\leq \frac{N^{1-\psi_f}}{\sqrt{T}} \left\| \frac{\mathbf{D}}{T} \right\|_{\infty} \|\boldsymbol{\varepsilon}_i\|_{\infty} \\ &= O_p(1) \frac{N^{1-\psi_f}}{\sqrt{T}} \max_t |\varepsilon_{it}|. \end{aligned}$$

We get the final equality from the fact that \mathbf{D} is $L \times T$ matrix with all elements having bounded second moments given Assumptions 2 and 3. Hence, its L_{∞} norm will scale with at most T and therefore $\left\| \frac{\mathbf{D}}{T} \right\|_{\infty}$ will have a maximum order $O_p(1)$. Hence we have,

$$\max_i \left\| \frac{N^{1-\psi_f}}{\sqrt{T}} \frac{\mathbf{D}\boldsymbol{\varepsilon}_i}{T} \right\|_{\infty} \leq O_p(1) \frac{N^{1-\psi_f}}{\sqrt{T}} \max_{i,t} |\varepsilon_{it}|.$$

Under Assumption 10, we have $\frac{N^{1-\psi_f}}{\sqrt{T}} [(\log N)^{r_1} + (\log T)^{r_1}]$ is $O(1)$. Hence,

$$\max_i \left\| \frac{N^{1-\psi_f}}{\sqrt{T}} \frac{\mathbf{D}\boldsymbol{\varepsilon}_i}{T} \right\|_{\infty} \text{ is } O_p(1).$$

To show that $\max_i \mathcal{A}_{2i.3}$ is $O_p(1)$, we first show that $\max_i \left[\Xi_{NT} \left\| N^{-\psi_f} T^{-1} \boldsymbol{\Phi}'_f \mathbf{J}_N \boldsymbol{\varepsilon}' \mathbf{J}_T \boldsymbol{\varepsilon}_i \right\|_1 \right]$ is $O_p(1)$ given assumptions of our model. to do so, we derive the stochastic order of a generic $(m, 1)^{th}$ element of the $K_f \times 1$ matrix $(\max_i \Xi_{NT} N^{-\psi_f} T^{-1} \boldsymbol{\Phi}'_f \mathbf{J}_N \boldsymbol{\varepsilon}' \mathbf{J}_T \boldsymbol{\varepsilon}_i)$. Since K_f is finite and the stochastic order is invariant across $m \in \{1, \dots, K_f\}$, the stochastic order of a generic element will be equal to the stochastic order of the L_1 norm the matrix.

A generic $(m, 1)^{th}$ element of the $K_f \times 1$ matrix $(\max_i \Xi_{NT} N^{-\psi_f} T^{-1} \boldsymbol{\Phi}'_f \mathbf{J}_N \boldsymbol{\varepsilon}' \mathbf{J}_T \boldsymbol{\varepsilon}_i)$ is bounded

by

$$\begin{aligned}
& (\Xi_{NT} N^{-\psi_f/2} T^{-1/2}) \left(\max_i \left| N^{-\psi_f/2} T^{-1/2} \sum_{j,t} \phi_{jf}(m) \varepsilon_{jt} \varepsilon_{it} \right| \right) \\
& + (\Xi_{NT} N^{-1/2} T^{-1/2}) \left| N^{-\psi_f} \sum_l \phi_{lf}(m) \right| \left(\max_i \left| N^{-1/2} T^{-1/2} \sum_{j,t} \varepsilon_{it} \varepsilon_{jt} \right| \right) \\
& + (\Xi_{NT} N^{-\psi_f/2} T^{-1/2}) \left| N^{-\psi_f/2} T^{-1} \sum_{j,s} \phi_{jf}(m) \varepsilon_{js} \right| \left(\max_i \left| \sum_t \frac{1}{\sqrt{T}} \varepsilon_{it} \right| \right) \\
& + (\Xi_{NT} N^{-1/2} T^{-1}) \left| N^{-\psi_f} \sum_l \phi_{lf}(m) \right| \left| N^{-1/2} T^{-1/2} \sum_{j,s} \varepsilon_{js} \right| \left(\max_i \left| \sum_t \frac{1}{\sqrt{T}} \varepsilon_{it} \right| \right) \\
& = a + b + c + d.
\end{aligned}$$

By the definition of Ξ_{NT} , $\Xi_{NT} N^{-\psi_f/2} = O(1)$, which implies $a = O_p\left(\frac{(\log N)^{r_4}}{\sqrt{T}}\right)$ by Assumption 7.5. $b = O_p\left(\frac{(\log N)^{r_5}}{\sqrt{T}}\right)$ by Assumptions 2.2 and 7.6. $c = O_p\left(\frac{(\log N)^{r_2}}{\sqrt{T}}\right)$ by Assumption 3.7 and 7.3. $d = O_p\left(\frac{(\log N)^{r_2}}{T}\right)$ by Lemma 1.3 and Assumptions 2.2 and 7.3. Therefore, by Assumption 10, $\max_i \left[\Xi_{NT} \left\| N^{-\psi_f} T^{-1} \Phi'_f \mathbf{J}_N \boldsymbol{\varepsilon}' \mathbf{J}_T \boldsymbol{\varepsilon}_i \right\|_1 \right]$ is $O_p(1)$. Given Assumption 6, similar reasoning would establish, $\max_i \left[\Xi_{NT} T^{-1/2} \left\| N^{-\psi_f} T^{-1} \Phi'_g \mathbf{J}_N \boldsymbol{\varepsilon}' \mathbf{J}_T \boldsymbol{\varepsilon}_i \right\|_1 \right]$ is $O_p(1)$. Hence, we have

$$\begin{aligned}
& \Xi_{NT} \max_i \left\{ \left\| O_p(1) \left(N^{-\psi_f} T^{-1} \Phi'_f \mathbf{J}_N \boldsymbol{\varepsilon}' \mathbf{J}_T \boldsymbol{\varepsilon}_i \right) \right\|_1 + \left\| O_p(1) \left(N^{-\psi_f} T^{-1} \Phi'_g \mathbf{J}_N \boldsymbol{\varepsilon}' \mathbf{J}_T \boldsymbol{\varepsilon}_i \right) \right\|_1 \right\} \\
& \leq \|O_p(1)\|_1 \left(\max_i \left[\Xi_{NT} \left\| N^{-\psi_f} T^{-1} \Phi'_f \mathbf{J}_N \boldsymbol{\varepsilon}' \mathbf{J}_T \boldsymbol{\varepsilon}_i \right\|_1 \right] + \max_i \left[\Xi_{NT} T^{-1/2} \left\| N^{-\psi_f} T^{-1} \Phi'_g \mathbf{J}_N \boldsymbol{\varepsilon}' \mathbf{J}_T \boldsymbol{\varepsilon}_i \right\|_1 \right] \right) \\
& = O_p(1) + O_p(1).
\end{aligned}$$

Hence $\mathcal{A}_{2i} \cdot 3 = O_p(1)$.

For \mathcal{A}_{3i} , since $\frac{\Xi_{NT}}{T} \leq \frac{1}{\sqrt{T}}$, we have, $\left(\frac{\Xi_{NT}}{T}\right) \gamma'_s(\boldsymbol{\nu}_T \bar{\boldsymbol{\varepsilon}}_s)' \boldsymbol{\varepsilon}_i \leq \left(\frac{1}{\sqrt{T}}\right) \gamma'_s(\boldsymbol{\nu}_T \bar{\boldsymbol{\varepsilon}}_s)' \boldsymbol{\varepsilon}_i$ and we have

$$\left(\frac{1}{\sqrt{T}}\right) \gamma'_s(\boldsymbol{\nu}_T \bar{\boldsymbol{\varepsilon}}_s)' \boldsymbol{\varepsilon}_i = \sum_{j \in S} \gamma_j \bar{\varepsilon}_j \left(\frac{1}{\sqrt{T}} \sum_t \varepsilon_{it}\right).$$

Therefore,

$$\begin{aligned}
\max_i \left(\frac{1}{\sqrt{T}} \right) \gamma'_s (\iota_T \bar{\varepsilon}_s)' \varepsilon_i &\leq \sum_{j \in S} \gamma_j \bar{\varepsilon}_j \left(\max_i \left| \frac{1}{\sqrt{T}} \sum_t \varepsilon_{it} \right| \right) \\
&= \sum_{j \in S} O_p \left(\frac{1}{\sqrt{T}} \right) O_p((\log N)^{r_2}) \\
&= O_p \left(\frac{(\log N)^{r_2}}{\sqrt{T}} \right) \\
&= O_p(1),
\end{aligned}$$

where the second last line follows from Assumption 7 and Lemma 1.3. The second last line follows from the fact that the cardinality of S is bounded by Assumption 9. The final line follows from Assumption 10.

Using a similar logic, $\max_i \left(\frac{\Xi_{NT}}{T} \right) (\iota_T \bar{\eta})' \varepsilon_i$ is $O_p(1)$. Hence $\max_i \mathcal{A}_i = \max_i (\mathcal{A}_{1i} + \mathcal{A}_{2i} + \mathcal{A}_{3i} + \mathcal{A}_{4i})$ is $O_p(1)$.

Next, we show that $\max_i \mathcal{B}_i = O_p(1)$.

$$\begin{aligned}
\mathcal{B}_i &= \left(\frac{\Xi_{NT}}{T} \right) (\hat{\mathbf{y}}_f - \mathbf{y}_f)' \mathbf{J}_T \mathbf{g} \phi_{ig} \\
&= \Xi_{NT} \mathbf{O}_p(\Xi_{NT}^{-1}) (T^{-1} \mathbf{F}' \mathbf{J}_T \mathbf{g} \phi_{ig}) + O_p(1) \left(\frac{\Xi_{NT}}{T} \right) (\hat{\mathbf{F}}_C - \mathbf{\Lambda}_f \mathbf{\Delta}_f \mathcal{P}_f \mathbf{f}') \mathbf{J}_T \mathbf{g} \phi_{ig} \\
&\quad + \left(\frac{\Xi_{NT}}{T} \right) \gamma'_s (\iota_T \bar{\varepsilon}_s)' \mathbf{J}_T \mathbf{g} \phi_{ig} + \left(\frac{\Xi_{NT}}{T} \right) (\iota_T \bar{\eta})' \mathbf{J}_T \mathbf{g} \phi_{ig} \\
&= \mathcal{B}_{1i} + \mathcal{B}_{2i} + \mathcal{B}_{3i} + \mathcal{B}_{4i}.
\end{aligned}$$

$\mathcal{B}_{1i} \dots \mathcal{B}_{4i}$ depend on i through ϕ_i only. Since $\forall m, \max_i \phi_i(m) = O_p(1)$ by Assumption 7.1, it suffices to show that $\mathcal{B}_{1i} + \mathcal{B}_{2i} + \mathcal{B}_{3i} + \mathcal{B}_{4i} = O_p(1)$ in order to prove $\max_i \mathcal{B}_i = O_p(1)$. $\mathcal{B}_{1i} = O_p(1)$ by assumption 2.1. \mathcal{B}_{3i} and \mathcal{B}_{4i} are $O_p(1)$ by Assumption 2.1 and lemmas 1.3

and 1.4. We show $\mathcal{B}_{2i} = O_p(1)$ below. Using Lemma 4, we can expand \mathcal{B}_{2i} as,

$$\begin{aligned}
\mathcal{B}_{2i} &= O_p(1) \left(\frac{\Xi_{NT}}{T} \right) \left(\hat{\mathbf{F}}_C - \mathbf{\Lambda}_f \mathbf{\Delta}_f \mathcal{P}_f \mathbf{f}' \right) \mathbf{J}_T \mathbf{g} \phi_{ig} \\
&= O_p(1) \Xi_{NT} \{ \mathbf{\Lambda} \left(N^{-\psi_f} T^{-1} \mathbf{F}' \mathbf{J}_T \mathbf{\varepsilon} \mathbf{J}_N \mathbf{\Phi} \right) (T^{-1} \mathbf{F}' \mathbf{J}_T \mathbf{g} \phi_{ig}) \\
&\quad + (T^{-1} \mathbf{\omega}' \mathbf{J}_T \mathbf{F}) \left(N^{-\psi_f} \mathbf{\Phi}' \mathbf{J}_N \mathbf{\Phi} \right) (T^{-1} \mathbf{F}' \mathbf{J}_T \mathbf{g} \phi_{ig}) + \left(N^{-\psi_f} T^{-1} \mathbf{\omega}' \mathbf{J}_T \mathbf{\varepsilon} \mathbf{J}_N \mathbf{\Phi} \right) (T^{-1} \mathbf{F}' \mathbf{J}_T \mathbf{g} \phi_{ig}) \\
&\quad + \zeta (T^{-1} \mathbf{\varepsilon}' \mathbf{J}_T \mathbf{F}) \left(N^{-\psi_f} \mathbf{\Phi}' \mathbf{J}_N \mathbf{\Phi} \right) (T^{-1} \mathbf{F}' \mathbf{J}_T \mathbf{g} \phi_{ig}) + \zeta \left(N^{-\psi_f} T^{-1} \mathbf{\varepsilon}' \mathbf{J}_T \mathbf{\varepsilon} \mathbf{J}_N \mathbf{\Phi} \right) (T^{-1} \mathbf{F}' \mathbf{J}_T \mathbf{g} \phi_{ig}) \\
&\quad + \mathbf{\Lambda} (T^{-1} \mathbf{F}' \mathbf{J}_T \mathbf{F}) \left(N^{-\psi_f} T^{-1} \mathbf{\Phi}' \mathbf{J}_N \mathbf{\varepsilon}' \mathbf{J}_T \mathbf{g} \phi_{ig} \right) + (T^{-1} \mathbf{\omega}' \mathbf{J}_T \mathbf{F}) \left(N^{-\psi_f} T^{-1} \mathbf{\Phi}' \mathbf{J}_N \mathbf{\varepsilon}' \mathbf{J}_T \mathbf{g} \phi_{ig} \right) \\
&\quad + \frac{N^{1-\psi_f}}{\sqrt{T}} \mathbf{\Lambda} \left(N^{-1} T^{-3/2} \mathbf{F}' \mathbf{J}_T \mathbf{\varepsilon} \mathbf{J}_N \mathbf{\varepsilon} \mathbf{J}_T \mathbf{g} \phi_{ig} \right) + \frac{N^{1-\psi_f}}{\sqrt{T}} \left(N^{-1} T^{-3/2} \mathbf{\omega}' \mathbf{J}_T \mathbf{\varepsilon} \mathbf{J}_N \mathbf{\varepsilon} \mathbf{J}_T \mathbf{g} \phi_{ig} \right) \\
&\quad + \frac{N^{1-\psi_f}}{\sqrt{T}} \zeta \left(N^{-1} T^{-3/2} \mathbf{\varepsilon}' \mathbf{J}_T \mathbf{\varepsilon} \mathbf{J}_N \mathbf{\varepsilon} \mathbf{J}_T \mathbf{g} \phi_{ig} \right) + \zeta (T^{-1} \mathbf{\varepsilon}' \mathbf{J}_T \mathbf{F}) \left(N^{-\psi_f} T^{-1} \mathbf{\Phi}' \mathbf{J}_N \mathbf{\varepsilon}' \mathbf{J}_T \mathbf{g} \phi_{ig} \right) \\
&\quad + \mathbf{\Lambda}_f (T^{-1} \mathbf{f}' \mathbf{J}_T \mathbf{f}) \left(N^{-\psi_f} \mathbf{\Phi}'_f \mathbf{J}_N \mathbf{\Phi}_g \right) (T^{-1} \mathbf{g}' \mathbf{J}_T \mathbf{g} \phi_{ig}) \\
&\quad + \mathbf{\Lambda}_f (T^{-1} \mathbf{f}' \mathbf{J}_T \mathbf{g}) \left(N^{-\psi_f} \mathbf{\Phi}'_g \mathbf{J}_N \mathbf{\Phi}_f \right) (T^{-1} \mathbf{f}' \mathbf{J}_T \mathbf{g} \phi_{ig}) \\
&\quad + \frac{N^{\psi_g - \psi_f}}{\sqrt{T}} \mathbf{\Lambda}_f \left(T^{-1/2} \mathbf{f}' \mathbf{J}_T \mathbf{g} \right) \left(N^{-\psi_g} \mathbf{\Phi}'_g \mathbf{J}_N \mathbf{\Phi}_g \right) (T^{-1} \mathbf{g}' \mathbf{J}_T \mathbf{g} \phi_{ig}) \} \\
&= O_p(1) \Xi_{NT} \mathbf{O}_p(\Xi_{NT}^{-1}) = O_p(1).
\end{aligned}$$

The final line follows from Lemma 2 and 6 and the fact that ζ has finitely many non-zero entries by Assumption 9.

$\max_i \mathcal{C}_i = O_p(1)$ follows from similar argument as for $\max_i \mathcal{A}_i = O_p(1)$. $\max_i \mathcal{C}_i = \max_i \boldsymbol{\gamma}' (\hat{\boldsymbol{\varepsilon}} - \boldsymbol{\varepsilon})' \boldsymbol{\varepsilon}_i = \max_i \boldsymbol{\gamma}'_S (\hat{\boldsymbol{\varepsilon}}_S - \boldsymbol{\varepsilon}_S)' \boldsymbol{\varepsilon}_i$. The expression for $\hat{\boldsymbol{\varepsilon}}_S - \boldsymbol{\varepsilon}_S$ can be obtained using lemma 9 as $\forall i \in S$, $\phi_{ig} = 0$. The proof then follows similar steps as for \mathcal{A}_i .

Similarly, $\max_i \mathcal{D}_i = O_p(1)$ follows from an analogous argument as for $\max_i \mathcal{B}_i = O_p(1)$.

Therefore $\text{II} = \max_i (\mathcal{A}_i + \mathcal{B}_i + \mathcal{C}_i + \mathcal{D}_i)$ is $O_p(1)$.

We now show item III : $\left(\frac{\Xi_{NT}}{T} \right) \max_i (\hat{\boldsymbol{\varepsilon}}_i - (\boldsymbol{\varepsilon}_i + \mathbf{J}_T \mathbf{g} \phi_{ig}))' \boldsymbol{\eta}$ is $O_p(1)$.

From the discussion leading upto lemma 9, we can express $\left(\frac{\Xi_{NT}}{T} \right) \max_i (\hat{\boldsymbol{\varepsilon}}_i - (\boldsymbol{\varepsilon}_i + \mathbf{J}_T \mathbf{g} \phi_{ig}))' \boldsymbol{\eta}$

as a sum of three terms.

$$\begin{aligned}
& \max_i \left(\frac{\Xi_{NT}}{T} \right) (\hat{\varepsilon}_i - (\varepsilon_i + \mathbf{J}_T \mathbf{g} \phi_{ig}))' \boldsymbol{\eta} \\
&= \max_i \left(N^{-\psi_f} T^{-2} \mathbf{W}'_{XZ} \mathbf{S}_{X\mathbf{x}_i} - \boldsymbol{\Lambda}_f \boldsymbol{\Delta}_f \mathcal{P}_f \boldsymbol{\Delta}_f \phi_{if} \right)' \mathcal{O}_p(1) \boldsymbol{\Lambda}_f \boldsymbol{\Delta}_f \mathcal{P}_f \frac{\mathbf{f}' \mathbf{J}_T \boldsymbol{\eta}}{T} \Xi_{NT} \\
&\quad + \max_i \left(\boldsymbol{\Lambda}_f \boldsymbol{\Delta}_f \mathcal{P}_f \boldsymbol{\Delta}_f \phi_{if} \right)' \mathcal{O}_p(1) (\hat{\mathbf{F}}_C - \boldsymbol{\Lambda}_f \boldsymbol{\Delta}_f \mathcal{P}_f \mathbf{f}') \mathbf{J}_T \boldsymbol{\eta} \left(\frac{\Xi_{NT}}{T} \right) \\
&\quad + \mathcal{O}_p(\Xi_{NT}^{-1}) \left(\frac{\Xi_{NT}}{T} \sum_t \eta_{t+h} \right) \\
&= \mathcal{P} + \mathcal{Q} + \mathcal{R}.
\end{aligned}$$

Since $\frac{\Xi_{NT}}{T} \leq \frac{1}{\sqrt{T}}$, we have $\boldsymbol{\Lambda}_f \boldsymbol{\Delta}_f \mathcal{P}_f \frac{\mathbf{f}' \mathbf{J}_T \boldsymbol{\eta}}{T} \Xi_{NT} \leq \boldsymbol{\Lambda}_f \boldsymbol{\Delta}_f \mathcal{P}_f \frac{\mathbf{f}' \mathbf{J}_T \boldsymbol{\eta}}{\sqrt{T}} = \mathcal{O}_p(1)$ by Lemma 1.2. Therefore we have $\mathcal{P} = \max_i (N^{-\psi_f} T^{-2} \mathbf{W}'_{XZ} \mathbf{S}_{X\mathbf{x}_i} - \boldsymbol{\Lambda}_f \boldsymbol{\Delta}_f \mathcal{P}_f \boldsymbol{\Delta}_f \phi_{if})' \mathcal{O}_p(1)$. We need to show that $\max_i (N^{-\psi_f} T^{-2} \mathbf{W}'_{XZ} \mathbf{S}_{X\mathbf{x}_i} - \boldsymbol{\Lambda}_f \boldsymbol{\Delta}_f \mathcal{P}_f \boldsymbol{\Delta}_f \phi_{if}) = \mathcal{O}_p(1)$.

$$\begin{aligned}
& N^{-\psi_f} T^{-2} \mathbf{W}'_{XZ} \mathbf{S}_{X\mathbf{x}_i} - \boldsymbol{\Lambda}_f \boldsymbol{\Delta}_f \mathcal{P}_f \boldsymbol{\Delta}_f \phi_{if} \\
&= \boldsymbol{\Lambda} (T^{-1} \mathbf{F}' \mathbf{J}_T \mathbf{F}) \left(N^{-\psi_f} \boldsymbol{\Phi}' \mathbf{J}_N \boldsymbol{\Phi} \right) (T^{-1} \mathbf{F}' \mathbf{J}_T \boldsymbol{\varepsilon}_i) \\
&\quad + \boldsymbol{\Lambda} (T^{-1} \mathbf{F}' \mathbf{J}_T \mathbf{F}) \left(N^{-\psi_f} T^{-1} \boldsymbol{\Phi}' \mathbf{J}_N \boldsymbol{\varepsilon}' \mathbf{J}_T \boldsymbol{\varepsilon}_i \right) \\
&\quad + \boldsymbol{\Lambda} \left(N^{-\psi_f} T^{-1} \mathbf{F}' \mathbf{J}_T \boldsymbol{\varepsilon} \mathbf{J}_N \boldsymbol{\Phi} \right) (T^{-1} \mathbf{F}' \mathbf{J}_T \boldsymbol{\varepsilon}_i) \\
&\quad + \frac{N^{1-\psi_f}}{\sqrt{T}} \boldsymbol{\Lambda} \left(N^{-1} T^{-3/2} \mathbf{F}' \mathbf{J}_T \boldsymbol{\varepsilon} \mathbf{J}_N \boldsymbol{\varepsilon}' \mathbf{J}_T \boldsymbol{\varepsilon}_i \right) \\
&\quad + \frac{N^{1-\psi_f}}{\sqrt{T}} \left(N^{-1} T^{-3/2} \boldsymbol{\omega}' \mathbf{J}_T \boldsymbol{\varepsilon} \mathbf{J}_N \boldsymbol{\varepsilon}' \mathbf{J}_T \boldsymbol{\varepsilon}_i \right) \\
&\quad + (T^{-1} \boldsymbol{\omega}' \mathbf{J}_T \mathbf{F}) \left(N^{-\psi_f} T^{-1} \boldsymbol{\Phi}' \mathbf{J}_N \boldsymbol{\varepsilon}' \mathbf{J}_T \boldsymbol{\varepsilon}_i \right) \\
&\quad + \left(N^{-\psi_f} T^{-1} \boldsymbol{\omega}' \mathbf{J}_T \boldsymbol{\varepsilon} \mathbf{J}_N \boldsymbol{\Phi} \right) (T^{-1} \mathbf{F}' \mathbf{J}_T \boldsymbol{\varepsilon}_i) \\
&\quad + (T^{-1} \mathbf{F}' \mathbf{J}_T \boldsymbol{\omega}) \left(N^{-\psi_f} \boldsymbol{\Phi}' \mathbf{J}_N \boldsymbol{\Phi} \right) (T^{-1} \mathbf{F}' \mathbf{J}_T \boldsymbol{\varepsilon}_i) \\
&\quad + \mathcal{O}_p(\Xi_{NT}^{-1}) \phi_i.
\end{aligned}$$

The last term $\mathcal{O}_p(\Xi_{NT}^{-1}) \phi_i$ captures all the terms in the expansion which have a maximum order of Ξ_{NT}^{-1} and depend on i through ϕ_i only. Therefore $\max_i (N^{-\psi_f} T^{-2} \mathbf{W}'_{XZ} \mathbf{S}_{X\mathbf{x}_i} - \boldsymbol{\Lambda}_f \boldsymbol{\Delta}_f \mathcal{P}_f \boldsymbol{\Delta}_f \phi_{if}) = \mathcal{O}_p(1)$ since $\max_i \phi_i$ is $\mathcal{O}_p(1)$ by Assumption 7.1. Stochastic order for the max of other terms follows similar arguments as in Item I for the term \mathcal{A} .

For \mathcal{Q} , note that since $\max_i \mathbf{\Lambda}_f \mathbf{\Delta}_f \mathcal{P}_f \mathbf{\Delta}_f \phi_{if} = O_p(1)$ by Assumption 7.1, it suffices to show that $\left(\hat{\mathbf{F}}_C - \mathbf{\Lambda}_f \mathbf{\Delta}_f \mathcal{P}_f \mathbf{f}' \right) \mathbf{J}_T \boldsymbol{\eta} \left(\frac{\Xi_{NT}}{T} \right) = O_p(1)$, which we show below.

$$\begin{aligned}
& \frac{\Xi_{NT}}{T} \left(\hat{\mathbf{F}}_C - \mathbf{\Lambda}_f \mathbf{\Delta}_f \mathcal{P}_f \mathbf{f}' \right) \mathbf{J}_T \boldsymbol{\eta} \\
&= \mathbf{\Lambda} \left(T^{-1} \mathbf{F}' \mathbf{J}_T \mathbf{F} \right) \left(N^{-\psi_f} \left(\frac{\Xi_{NT}}{T} \right) \boldsymbol{\Phi}' \mathbf{J}_N \boldsymbol{\varepsilon}' \mathbf{J}_T \boldsymbol{\eta} \right) \\
&+ \mathbf{\Lambda} \left(N^{-\psi_f} T^{-1} \mathbf{F}' \mathbf{J}_T \boldsymbol{\varepsilon} \mathbf{J}_N \boldsymbol{\Phi} \right) \left(\left(\frac{\Xi_{NT}}{T} \right) \mathbf{F}' \mathbf{J}_T \boldsymbol{\eta} \right) + (T^{-1} \boldsymbol{\omega}' \mathbf{J}_T \mathbf{F}) \left(N^{-\psi_f} \boldsymbol{\Phi}' \mathbf{J}_N \boldsymbol{\Phi} \right) \left(\left(\frac{\Xi_{NT}}{T} \right) \mathbf{F}' \mathbf{J}_T \boldsymbol{\eta} \right) \\
&+ \left(N^{-\psi_f} T^{-1} \boldsymbol{\omega}' \mathbf{J}_T \boldsymbol{\varepsilon} \mathbf{J}_N \boldsymbol{\Phi} \right) \left(\left(\frac{\Xi_{NT}}{T} \right) \mathbf{F}' \mathbf{J}_T \boldsymbol{\eta} \right) + \boldsymbol{\zeta} (T^{-1} \boldsymbol{\varepsilon}' \mathbf{J}_T \mathbf{F}) \left(N^{-\psi_f} \boldsymbol{\Phi}' \mathbf{J}_N \boldsymbol{\Phi} \right) \left(\left(\frac{\Xi_{NT}}{T} \right) \mathbf{F}' \mathbf{J}_T \boldsymbol{\eta} \right) \\
&+ \boldsymbol{\zeta} \left(N^{-\psi_f} T^{-1} \boldsymbol{\varepsilon}' \mathbf{J}_T \boldsymbol{\varepsilon} \mathbf{J}_N \boldsymbol{\Phi} \right) \left(\left(\frac{\Xi_{NT}}{T} \right) \mathbf{F}' \mathbf{J}_T \boldsymbol{\eta} \right) + \Xi_{NT} \mathbf{\Lambda} (T^{-1} \mathbf{F}' \mathbf{J}_T \mathbf{F}) \left(N^{-\psi_f/2} T^{-1} \boldsymbol{\Phi}' \mathbf{J}_N \boldsymbol{\varepsilon}' \mathbf{J}_T \boldsymbol{\eta} \right) \\
&+ \left(\left(\frac{\Xi_{NT}}{T} \right) \boldsymbol{\omega}' \mathbf{J}_T \mathbf{F} \right) \left(N^{-\psi_f} T^{-1} \boldsymbol{\Phi}' \mathbf{J}_N \boldsymbol{\varepsilon}' \mathbf{J}_T \boldsymbol{\eta} \right) + \Xi_{NT} \frac{N^{1-\psi_f}}{\sqrt{T}} \mathbf{\Lambda} \left(N^{-1} T^{-3/2} \mathbf{F}' \mathbf{J}_T \boldsymbol{\varepsilon} \mathbf{J}_N \boldsymbol{\varepsilon} \mathbf{J}_T \boldsymbol{\eta} \right) \\
&+ \Xi_{NT} \frac{N^{1-\psi_f}}{\sqrt{T}} \left(N^{-1} T^{-1/2} \boldsymbol{\omega}' \mathbf{J}_T \boldsymbol{\varepsilon} \mathbf{J}_N \boldsymbol{\varepsilon} \mathbf{J}_T \boldsymbol{\eta} \right) + \Xi_{NT} \frac{N^{1-\psi_f}}{\sqrt{T}} \boldsymbol{\zeta} \left(N^{-1} T^{-1/2} \boldsymbol{\varepsilon}' \mathbf{J}_T \boldsymbol{\varepsilon} \mathbf{J}_N \boldsymbol{\varepsilon} \mathbf{J}_T \boldsymbol{\eta} \right) \\
&+ \mathbf{\Lambda}_f (T^{-1} \mathbf{f}' \mathbf{J}_T \mathbf{f}) \left(N^{-\psi_f} \boldsymbol{\Phi}'_f \mathbf{J}_N \boldsymbol{\Phi}_g \right) \left(\left(\frac{\Xi_{NT}}{T} \right) \mathbf{g}' \mathbf{J}_T \boldsymbol{\eta} \right) \\
&+ \mathbf{\Lambda}_f (T^{-1} \mathbf{f}' \mathbf{J}_T \mathbf{g}) \left(N^{-\psi_f} \boldsymbol{\Phi}'_g \mathbf{J}_N \boldsymbol{\Phi}_f \right) \left(\left(\frac{\Xi_{NT}}{T} \right) \mathbf{f}' \mathbf{J}_T \boldsymbol{\eta} \right) \\
&+ \frac{N^{\psi_g - \psi_f}}{\sqrt{T}} \mathbf{\Lambda}_f \left(T^{-1/2} \mathbf{f}' \mathbf{J}_T \mathbf{g} \right) \left(N^{-\psi_g} \boldsymbol{\Phi}'_g \mathbf{J}_N \boldsymbol{\Phi}_g \right) \left(\left(\frac{\Xi_{NT}}{T} \right) \mathbf{g}' \mathbf{J}_T \boldsymbol{\eta} \right) \\
&= O_p(1).
\end{aligned}$$

Since $\frac{\Xi_{NT}}{T} \leq \frac{1}{\sqrt{T}}$ and $\frac{N^{1-\psi_f}}{\sqrt{T}} = O(1)$, the final equality comes from rates derived in Lemma 2, 6, employing the fact that $\boldsymbol{\zeta}$ has finitely many non-zero entries by Assumption 9. $\text{IV} = O_p(1)$ can be deduced similarly and this concludes the proof.

Theorem 5 Let the regularization parameter in Stage-2 Pass 1 regression be given by $\lambda := 2 \frac{\sqrt{c + \kappa \log N}}{\Xi_{NT}}$, $c > 0$ and κ is defined in assumption 10. Then, if Assumptions 1-10 hold, w.p at least $1 - \exp \left[-\frac{c}{\kappa} \right] + o(1)$, we have,

$$\frac{1}{T} \|\hat{\boldsymbol{\varepsilon}} \hat{\boldsymbol{\gamma}} - \boldsymbol{\varepsilon} \boldsymbol{\gamma}\|_2 = O_p \left(\frac{\sqrt{\log N}}{\Xi_{NT}} \right).$$

Proof: First stage regression gives initial forecast $\hat{\mathbf{y}}_f = \boldsymbol{\nu}_T \bar{\mathbf{y}} + \mathbf{J}_T \hat{\mathbf{F}} \hat{\boldsymbol{\beta}}$. Let $\hat{\mathbf{u}} = (\hat{u}_{1+h}, \dots, \hat{u}_{T+h})'$ denote the vector of stacked residuals from the first stage regression. $\hat{\mathbf{u}} = \mathbf{y} - \hat{\mathbf{y}}_f = \mathbf{y} - \boldsymbol{\nu}_T \bar{\mathbf{y}} - \mathbf{J}_T \hat{\mathbf{F}} \hat{\boldsymbol{\beta}}$. The second stage involves the Lasso regression of $\hat{\mathbf{u}}$ on $\hat{\boldsymbol{\varepsilon}}$, where both

$\hat{\mathbf{u}}$ and $\hat{\boldsymbol{\varepsilon}}$ are generated regressors ,i.e., $\boldsymbol{\gamma}$ is estimated by the following penalized regression,

$$\hat{\boldsymbol{\gamma}} = \arg \min_{\boldsymbol{\gamma}} \left\{ \|\hat{\mathbf{u}} - \hat{\boldsymbol{\varepsilon}}\boldsymbol{\gamma}\|_2^2/T + \lambda \|\boldsymbol{\gamma}\|_1 \right\}.$$

The lasso solution must satisfy

$$\|\hat{\mathbf{u}} - \hat{\boldsymbol{\varepsilon}}\hat{\boldsymbol{\gamma}}\|_2^2/T + \lambda \|\hat{\boldsymbol{\gamma}}\|_1 \leq \|\hat{\mathbf{u}} - \hat{\boldsymbol{\varepsilon}}\boldsymbol{\gamma}\|_2^2/T + \lambda \|\boldsymbol{\gamma}\|_1. \quad (\text{A4.2})$$

Since $\tilde{\boldsymbol{\eta}} = \hat{\mathbf{u}} - \hat{\boldsymbol{\varepsilon}}\boldsymbol{\gamma}$ (Defined in Lemma 9), Equation A4.2 can be written as,

$$\frac{(\hat{\mathbf{u}} - \hat{\boldsymbol{\varepsilon}}\hat{\boldsymbol{\gamma}} - \tilde{\boldsymbol{\eta}})'(\hat{\mathbf{u}} - \hat{\boldsymbol{\varepsilon}}\hat{\boldsymbol{\gamma}} + \tilde{\boldsymbol{\eta}})}{T} + \lambda \|\hat{\boldsymbol{\gamma}}\|_1 - \lambda \|\boldsymbol{\gamma}\|_1 \leq 0.$$

Substituting values of $\tilde{\boldsymbol{\eta}}$ and $\hat{\mathbf{u}}$, this simplifies to

$$\frac{(-\hat{\boldsymbol{\varepsilon}}(\hat{\boldsymbol{\gamma}} - \boldsymbol{\gamma}))'(-\hat{\boldsymbol{\varepsilon}}(\hat{\boldsymbol{\gamma}} - \boldsymbol{\gamma}) + 2\tilde{\boldsymbol{\eta}})}{T} + \lambda \|\hat{\boldsymbol{\gamma}}\|_1 - \lambda \|\boldsymbol{\gamma}\|_1 \leq 0.$$

This gives the “Basic Inequality” for Lasso. See [Bühlmann & Van De Geer \[2011\]](#) (Page 103)

$$\|\hat{\boldsymbol{\varepsilon}}(\hat{\boldsymbol{\gamma}} - \boldsymbol{\gamma})\|_2^2/T + \lambda \|\hat{\boldsymbol{\gamma}}\|_1 \leq 2(\hat{\boldsymbol{\gamma}} - \boldsymbol{\gamma})' \hat{\boldsymbol{\varepsilon}}' \tilde{\boldsymbol{\eta}}/T + \lambda \|\boldsymbol{\gamma}\|_1.$$

Note that,

$$2|(\hat{\boldsymbol{\gamma}} - \boldsymbol{\gamma})' \hat{\boldsymbol{\varepsilon}}' \tilde{\boldsymbol{\eta}}| \leq \left(\max_{1 \leq j \leq N} 2|\hat{\boldsymbol{\varepsilon}}'_j \tilde{\boldsymbol{\eta}}| \right) \|\hat{\boldsymbol{\gamma}} - \boldsymbol{\gamma}\|_1.$$

Next, we show that for an appropriate choice λ_0 the set

$$\mathcal{T} := \left\{ \max_{1 \leq j \leq N} \frac{2|\hat{\boldsymbol{\varepsilon}}'_j \tilde{\boldsymbol{\eta}}|}{T} \leq \lambda_0 \right\}$$

has a high probability.

Let $\lambda_0 := \frac{\sqrt{c + \kappa \log N}}{\Xi_{NT}}$, From Assumption 10,

$$\begin{aligned}
\mathbb{P}(\mathcal{T}) &= \mathbb{P}\left(\max_{1 \leq j \leq N} \frac{2|\hat{\epsilon}'_j \tilde{\eta}|}{T} \leq \frac{\sqrt{c + \kappa \log N}}{\Xi_{NT}}\right) \\
&= 1 - \mathbb{P}\left(\max_{1 \leq j \leq N} \frac{\Xi_{NT}}{T} 2|\hat{\epsilon}'_j \tilde{\eta}| \geq \sqrt{c + \kappa \log N}\right) \\
&\geq 1 - \mathbb{P}\left(\max_{1 \leq j \leq N} \frac{2|\hat{\epsilon}'_j \tilde{\eta}|}{\sqrt{T}} \geq \sqrt{c + \kappa \log N}\right) \\
&\geq 1 - \mathbb{P}\left(\left(\max_{1 \leq j \leq N} \frac{2|\epsilon'_j \eta|}{\sqrt{T}}\right) + |O_p(1)| \geq \sqrt{c + \kappa \log N}\right) \\
&\geq 1 - N \exp\left[\frac{-(c + \kappa \log N)}{\kappa}\right] + o(1) \\
&= 1 - \left(\exp\left(\frac{-c}{\kappa}\right) + o(1)\right).
\end{aligned}$$

The third inequality follows from the fact that $\frac{\Xi_{NT}}{T} \leq \frac{1}{\sqrt{T}}$, the fourth inequality comes from Lemma 10 and the final inequality is by Assumption 10. By making c arbitrarily large, the probability can be made arbitrarily small.

We have on \mathcal{T} , with $\lambda = 2\lambda_0$,

$$2 \frac{\|\hat{\epsilon}(\hat{\gamma} - \gamma)\|_2^2}{T} + \lambda \|\hat{\gamma}_{sc}\|_1 \leq 3\lambda \|\hat{\gamma}_s - \gamma_s\|_1. \quad (\text{A4.3})$$

Proof: See Lemma 6.3, page 105, [Bühlmann & Van De Geer \[2011\]](#).

Define $\Delta_{\hat{\epsilon}} := \hat{\epsilon}'\hat{\epsilon}/T$. Given that the set of ‘relevant’ idiosyncratic terms S has a fixed cardinality, it is easy to show that if the comparability condition for set S , holds w.r.t $\Delta_{\epsilon, g}$ (defined in Assumption 10(c)) it implies that the compatibility condition also holds for set S w.r.t $\Delta_{\hat{\epsilon}}$.

Proof: Through similar steps as in Lemma 10, we can show that

$$\max_{ij} \left(\frac{1}{T}\right) \hat{\epsilon}'_i \hat{\epsilon}_j = \max_{ij} \left(\frac{(\epsilon_i + \mathbf{J}_T \mathbf{g} \Phi_{ig})'(\epsilon_j + \mathbf{J}_T \mathbf{g} \Phi_{jg})}{T}\right) + o_p(1). \quad (\text{A4.4})$$

Hence,

$$\max_{ij} \Delta_{\hat{\epsilon}}^{ij} = \max_{ij} \Delta_{\epsilon, g}^{ij} + o_p(1). \quad (\text{A4.5})$$

Compatibility condition for set S w.r.t $\Delta_{\epsilon, g}$ implies, for all $N \times 1$ vectors Θ satisfying

$\|\Theta_{S^c}\|_1 < 3\|\Theta_S\|_1$, we have,

$$\|\Theta_S\|_1^2 < (\Theta' \Delta_{\varepsilon, g} \Theta) |S| / \nu_0^2,$$

which equivalently can be stated as,

$$1 < \frac{(\Theta' \Delta_{\varepsilon, g} \Theta) |S|}{\|\Theta_S\|_1^2 \nu_0^2}.$$

Therefore we have,

$$\begin{aligned} 1 &< \frac{(\Theta' \Delta_{\varepsilon, g} \Theta) |S|}{\|\Theta_S\|_1^2 \nu_0^2} \\ &< C_o \sum_{i,j} \frac{\Theta_i \Theta_j}{\|\Theta_S\|_1^2} (\Delta_{\varepsilon, g}^{ij}) \\ &< C_o \sum_{i,j} \frac{\Theta_i \Theta_j}{\|\Theta_S\|_1^2} (\Delta_{\hat{\varepsilon}}^{ij}) + \max_{ij} C_o (\Delta_{\varepsilon, g}^{ij} - \Delta_{\hat{\varepsilon}}^{ij}) \sum_{i,j} \frac{\Theta_i \Theta_j}{\|\Theta_S\|_1^2} \\ &< C_o \sum_{i,j} \frac{\Theta_i \Theta_j}{\|\Theta_S\|_1^2} (\Delta_{\hat{\varepsilon}}^{ij}) + o_p(1) O(1) \\ &< C_o \sum_{i,j} \frac{\Theta_i \Theta_j}{\|\Theta_S\|_1^2} (\Delta_{\hat{\varepsilon}}^{ij}) + o_p(1). \end{aligned} \tag{A4.6}$$

The second last line follows from [A4.5](#). $C_o = \frac{|S|}{\nu_0^2}$ is a constant. $\sum_{i,j} \frac{\Theta_i \Theta_j}{\|\Theta_S\|_1^2}$ is bounded since we need to look at only those vectors which satisfy $\|\Theta_{S^c}\|_1 < 3\|\Theta_S\|_1$. Therefore, compatibility condition for the S w.r.t $\Delta_{\varepsilon, g}$ implies that compatibility condition for the S holds w.r.t $\Delta_{\hat{\varepsilon}}$ with probability approaching one.

Using equation [A4.3](#) and Assumption [10\(b\)](#), [A4.6](#), we have, on \mathcal{T} , with probability approaching one, for $\lambda = 2\lambda_0$,

$$\|\hat{\varepsilon}(\hat{\gamma} - \gamma)\|_2^2 / T + \lambda \|\hat{\gamma} - \gamma\|_1 \leq 4\lambda^2 |S| / \nu_0^2. \tag{A4.7}$$

Proof:

$$\begin{aligned}
2 \|\hat{\varepsilon}(\hat{\gamma} - \gamma)\|_2^2 / T + \lambda \|\hat{\gamma} - \gamma\|_1 &= 2 \|\hat{\varepsilon}(\hat{\gamma} - \gamma)\|_2^2 / T + \lambda \|\hat{\gamma}_s - \gamma_s\|_1 + \lambda \|\hat{\gamma}_{s^c}\|_1 \\
&\leq 4\lambda \|\hat{\gamma}_s - \gamma_s\|_1 \\
&\leq 4\lambda \sqrt{|S|} \|\hat{\varepsilon}(\hat{\gamma} - \gamma)\|_2 / (\sqrt{T}\nu_0) \\
&\leq \|\hat{\varepsilon}(\hat{\gamma} - \gamma)\|_2^2 / T + 4\lambda^2 |S| / \nu_0^2.
\end{aligned}$$

where we have used equation A4.3 in the first inequality and the compatibility condition (Assumption 10) is used in the second inequality.[¶] The Last inequality uses that fact that for any u, v , $4uv \leq u^2 + 4v^2$.

Concluding from the discussion above, we have that, Using the regularization parameter $\lambda = 2\lambda_0$, on the set \mathcal{T} , w.p approaching one, we have

$$\begin{aligned}
\|\hat{\varepsilon}(\hat{\gamma} - \gamma)\|_2^2 / T &\leq 4\lambda^2 |S| / \nu_0^2 \\
&= O_p(\lambda^2) \\
&= O_p\left(\frac{\log N}{\Xi_{NT}^2}\right). \tag{A4.8}
\end{aligned}$$

The final equality uses the fact that $|S|$ is finite. Finally, using triangle inequality we have,

$$\begin{aligned}
\frac{1}{T} \|\hat{\varepsilon}\hat{\gamma} - \varepsilon\gamma\|_2 &\leq \frac{1}{T} \|\hat{\varepsilon}\hat{\gamma} - \hat{\varepsilon}\gamma\|_2 + \frac{1}{T} \|(\hat{\varepsilon}_s - \varepsilon_s) \gamma_s\|_2 \\
&\leq \frac{1}{T} \|\hat{\varepsilon}\hat{\gamma} - \hat{\varepsilon}\gamma\|_2 + O_p(\Xi_{NT}^{-1}) \\
&= O_p\left(\frac{\sqrt{\log N}}{\Xi_{NT}}\right) + O_p(\Xi_{NT}^{-1}) \\
&= O_p\left(\frac{\sqrt{\log N}}{\Xi_{NT}}\right).
\end{aligned}$$

We have used triangle inequality in first step and Lemma 9 in the second step, noting that for $j \in \{i | \gamma_i \neq 0\}$, $\phi_{jg} = 0$ by Assumption 1. The third step invokes equation A4.8.

Corollary 5.1 follows directly using triangle inequality combining Theorem 5 and 1 (b).

[¶]In the compatibility condition we have used $\Theta = \hat{\gamma} - \gamma$ since $\hat{\gamma} - \gamma$ satisfies the condition $\|\hat{\gamma}_{s^c} - \gamma_{s^c}\|_1 = \|\hat{\gamma}_{s^c}\|_1 \leq 3 \|\hat{\gamma}_s - \gamma_s\|_1$ by A4.3

Notes: $K_f, K_g, \rho_f, \rho_g, a, d, \psi_f, \psi_g$, Oracle denotes the infeasible R^2 as described in Section 5 of the main paper. PCR denotes the regression of y on first ' K ' Principal components, where $K = K_f + K_g$. 3PRF denotes the auto-proxy 3PRF with K_f auto-proxies. Lasso denotes the R^2 from the Lasso regression of \mathbf{y} on \mathbf{X} . 3PRF+L is 3PRF-Lasso procedure where first stage 3PRF uses K_f proxies. PCR+L is analogously PCR $K = K_f + K_g$ PCs in the first stage regression, augmented with second stage lasso step. The highest R^2 value across competing methods is in bold.

Notes: TPR and FPR are defined similarly as in notes of Table A11. The values of ρ may appear arbitrarily chosen, but they result from a 2-step process.

We generate the covariance matrix of the 105 predictors by combining two block diagonal matrices. The covariance matrix of the relevant predictors is a 5×5 identity matrix \mathbb{I}_5 , while the covariance matrix of irrelevant predictors is obtained as $\mathbb{I}_{100} + \rho_1 \mathbf{v}_{100} \mathbf{v}_{100}'$, where \mathbb{I}_{100} is identity matrix of order 100 and \mathbf{v}_{100} denotes a 100×1 vector of ones. We allow ρ_1 to take values from the set 0, 0.2, 0.4, 0.6, 0.8, 1, 1.2, 1.5, 1.8. Finally, we combine both of these blocks to generate the covariance matrix of all 105 variables. To eliminate any scale effects, we standardize our variables. Standardization ensures that all variables have unit variance, and for the irrelevant predictors, the covariance (ρ_1) on the off-diagonal is replaced by correlation $\rho = \frac{\rho_1}{1 + \rho_1}$.
